Individuals understand and identify themselves in reference to groups. Social identities—national, ethnic, racial, gender, religious, occupational, and so on—comprise critical aspects of the self-concept and are derived from perceived membership of particular social groups. Originally developed to understand the psychological basis of intergroup discrimination, Henri Tajfel and John C. Turner's social identity theory describes processes significant for an individual's identification with large-scale social groups or categories. The social identification process starts from an "individual's subjective location" in the network of social relationships (Tajfel 1982, p. 503). Identification processes are experienced differently by individuals in terms of their locations in the hierarchically organized social relations of a society—as members of nations; as members of gender groups; as members of racial/ethnic groups; as members of religious groups; and in other social locations. After being categorized based on group membership, individuals seek to achieve positive self-esteem by differentiating their in-group (we/us) from a comparison out-group (them/others). This in-group/out-group comparison process reflects commonly shared ideas or attributions applied to social groups. In other words, the in-group bias leads to discrimination toward out-groups; at the same time, though, some group members identify themselves based in part on socially assigned but negative or undesirable attributions.

In her study of racial-identity development of minority adolescents, Beverly Tatum argues that adolescents of color are more likely to be actively engaged in exploration of their racial or ethnic identity than are white adolescents because they receive more intensive "racial content" messages from their surroundings and they perceive how their racial identity is presented to other racial group members (Tatum 1997, p. 54). In contrast, whites in the United

SOCIAL IDENTIFICATION
How do people perceive the self and what do they perceive as the self? People look outside of the self to the social context because the views of the self are shaped by the world individuals encounter. Social identification theories demonstrate how identity is defined, as a conception of the self, the content of the self, or the knowledge about who I am, constructed in terms of rules and orders applying to social contexts.

Symbolic interactionists have delineated the procedure of constructing the self-concept by evoking the significance of the relationship between the individual and the social structure. George Herbert Mead (1984) differentiates “me” from “I” to explain the concept of social self and how self is constructed through interactions with others. Charles Horton Cooley (1998) presents the concept of the “looking-glass self,” noting that the self is constituted through interaction with its surroundings and that the self-concept is achieved by speculating the imaginative evaluation from others. For Mead and Cooley, self is not an a priori or pre-given because it develops only through contact with others.

For Erving Goffman the construction of self is a series of presentations or performances to others: “The very structure of the self can be seen in terms of how we arrange for such performances” in the society (Goffman 1997, p. 23). Social interaction is viewed as a performance influenced by cultural environment, concerning the other people, constructed to provide appropriate impressions.

In this way, the individual develops identity by interacting with others, through presenting desirable impressions according to the social expectations in a particular socio-cultural context.

In *The Reproduction of Mothering* (1999) Nancy Chodorow provides a psychological analysis of the construction of gender identity in the intimate social surroundings of family. According to Chodorow, gender identity is the consequence of a specific family form in which women are exclusively responsible for the nurturing of children. Children build their gender identity by differentiating themselves from their primary caregivers, usually their mothers. Because the early social environment differs and is experienced differently by male and female children, Chodorow argues that individuals develop different gender identities based on sex. Her research has been particularly influential in explaining how patriarchal practices of Western cultures affect individual identification processes.

Individuals understand and identify themselves in reference to groups. Social identities—national, ethnic, racial, gender, religious, occupational, and so on—comprise critical aspects of the self-concept and are derived from perceived membership of particular social groups. Originally developed to understand the psychological basis of intergroup discrimination, Henri Tajfel and John C. Turner's social identity theory describes processes significant for an individual's identification with large-scale social groups or categories. The social identification process starts from an "individual's subjective location" in the network of social relationships (Tajfel 1982, p. 503). Identification processes are experienced differently by individuals in terms of their locations in the hierarchically organized social relations of a society—as members of nations; as members of gender groups; as members of racial/ethnic groups; as members of religious groups; and in other social locations. After being categorized based on group membership, individuals seek to achieve positive self-esteem by differentiating their in-group (we/us) from a comparison out-group (them/others). This in-group/out-group comparison process reflects commonly shared ideas or attributions applied to social groups. In other words, the in-group bias leads to discrimination toward out-groups; at the same time, though, some group members identify themselves based in part on socially assigned but negative or undesirable attributions.

In her study of racial-identity development of minority adolescents, Beverly Tatum argues that adolescents of color are more likely to be actively engaged in exploration of their racial or ethnic identity than are white adolescents because they receive more intensive “racial content” messages from their surroundings and they perceive how their racial identity is presented to other racial group members (Tatum 1997, p. 54). In contrast, whites in the United

States often deemphasize explicit racial content, partly because they take it for granted and are privileged through various social domains. Illustrating this, Eduardo Bonilla-Silva (2003) explores different dimensions of white privilege and demonstrates how whiteness is constructed in the U.S. society through narratives.

In a wide range of social settings, individuals struggle to establish social desirability or legitimacy of the identities they possess. Individuals recognize how the groups they belong to are perceived by other group members, and they react to this. Being a member of a particular group sometimes results in exaltation for the individual, but it can also result in unequal treatment, punishment, or marginalization. Distinctiveness often relates to the political boundaries established by the society. For example, identity politics postulates that difference is taken as a political motivation for action. Lesbian and gay activists struggle over their sexual identities to claim the same rights as heterosexuals to marriage, child-rearing, property ownership, and other social practices often forbidden to them.

In recent years social identification theories have expanded the range of research into interdisciplinary areas. Various social-scientific concepts and perspectives are increasingly incorporated as central aspects of social identification processes such as collective protest, political rhetoric, diversity, and system-justification beliefs (Hogg and Ridgeway 2003). However, social identification theories have been criticized for the treatment of identities as individual status categories, such as race/ethnic or gender categories. By focusing on the development of particular social-status categories, identification theorists often ignore structural issues, such as specific historical and cultural backgrounds or the political consequences of identification experiences in a given society. For instance, individual development of racial identity in the United States is deeply associated with the historical and cultural contexts of the United States. Through history, particular racial or ethnic groups have been projected with specific images, cultural notions, and political practices by other racial or ethnic groups. Thus, racial/ethnic identification processes not only mean developing social status categories at an individual level, but also imply structural power relations among racial/ethnic groups directly related to the historical and cultural context.

In the social sciences, studies use various methods—interviews, participant observation, ethnography, discourse analysis, survey, and experiments—to investigate the social identification process at the individual level and how this process is related to the social structure.

**SOCIAL INFLUENCE**

Of the myriad topics, questions, and issues of greatest moment to social psychologists, social influence has been the cornerstone of the field. From the earliest inception of modern social psychology, it has been the defining issue. For example, the first experiment in social psychology (Tripllett 1898) probed a phenomenon referred to as social facilitation—or the tendency for individuals engaging in like behavior to spur on the actions of one another. In this study, Norman Tripllett determined that the presence of a competing cyclist upped the level of performance of bicycle riders when compared to their performance levels as they pedaled against the clock. Similarly, Tripllett observed school-aged children who were instructed to turn fishing reels as fast as they could. He found that when they...
worked in pairs, their performance was superior to what it was when they worked alone.

As Aristotle (384–322 BCE) noted in detail, we are indeed social beings. The mere presence of others affects us beyond our awareness of those effects. The study of social influence has branched from simple demonstrations of socially facilitated behavior to research on such topics as attitude formation and change, conformity, group consensus, obedience, groupthink, prestige suggestion, political socialization, stereotype formation, and many other socially embedded consequences of social influence. This entry will focus on a description of social influence phenomena in the "classic" studies of and approaches to such influence. These classic studies will be separated into two categories: laboratory-experimental research and field-nonexperimental research.

CLASSIC LABORATORY-EXPERIMENTAL RESEARCH—SHERIF’S AUTOKINETIC EFFECT

If a stationary pinpoint of light is viewed in an otherwise completely dark room, the light will appear to move. This illusory effect, known as the autokinet effect, was used by Muzafer Sherif (1935) in early studies of social influence. Participants, who were not told that the light was actually stationary, were asked to indicate any movement they perceived by pressing a key that turned off the light. When a group of participants viewed the light at the same time, the fastest-acting participant turned off the light. After the light was turned off, the participants reported orally on the extent of movement. The results indicated that participants who viewed the light in groups showed a gradual convergence toward an agreed-upon extent of movement. Later, when tested alone, individuals continued giving the group-established judgment.

Sherif interpreted his results as indicating that the groups established a norm that influenced judgments. As will be discussed below, later researchers also emphasized the importance of norms as a determinant of social influence.

Asch’s Perceptual-Judgments Research Because Sherif’s demonstration of social influence involved public communication, it was more dramatic than the social influence that occurred in the social-facilitation paradigm. Still, the judgments were of an illusion. This was not the case, however, in an influential series of studies by Solomon Asch (1952). In Asch’s initial study, eight individuals, all but one of whom were confederates of the experimenter, made eighteen consecutive judgments in which they matched the length of a standard line with one of three comparison lines. On each of the eighteen trials, judgments were publicly announced in the order in which the group members sat, and the single naïve participant always sat next to last. On twelve of the trials, the confederates responded incorrectly. The results revealed marked individual differences, with three-fourths of the participants being influenced on at least one trial and one-third influenced on half or more of the trials.

Asch later reported a series of interesting follow-up experiments. In one such study, he found that the conformity effect was maximized with three confederates, was greatly reduced with two confederates, and all but disappeared with one confederate. In another study, he found that when a single confederate responded incorrectly in a group of participants, the confederate’s incorrect judgments created amusement and laughter. In still another study, he found that when the confederate who sat in the fourth position responded correctly, the social influence of the group on the participant sitting next to last was dramatically reduced. This latter finding is an early demonstration of minority influence—a topic later pursued by Serge Moscovici (1976, 1980) and others.

Milgram’s Obedience-to-Authority Research Asch’s research on perceptual judgment did produce dramatic results. However, momentary judgments regarding the perceived length of lines may, in the final analysis, be of no great import. Such is not the case, however, for Stanley Milgram’s (1965) research on obedience to authority.

Milgram’s initial idea was to provide a test of the extent to which individuals would harm someone when given direct orders to do so. History is replete with instances in which such cruelty has occurred. One of the more notable examples was the mass murdering of Jews at such German concentration camps as Auschwitz, Buchenwald, and Dachau during World War II (1939–1945). During the Vietnam War (1957–1975), there is the example of the 1968 My Lai massacre by American troops. A still more recent example is the murdering in 1978 of children and infants by parents and “nurses” at Jonestown in Guyana.

Milgram’s participants had responded to a newspaper advertisement to take part in a study of learning and memory at Yale University. They were all male and ranged in age between twenty and fifty years, and were of both white-collar and blue-collar backgrounds. Participants believed they were being tested in pairs, but one member of the pair was actually a confederate of the experimenter. Following a rigged drawing, the participant was assigned the role of “teacher” and the confederate was assigned the role of “learner” in a supposed test of the effect of punishment on memory. The participant-teacher witnessed the confederate-learner being strapped into an “electric chair” in a room immediately adjacent to the room containing the “shock-generator”—an apparatus containing a series...
of thirty switches that supposedly delivered increasingly intense shocks to the confederate-learner. The switches were accompanied by labels indicating increasing danger, finally ending with the label “XXX.” The participant-teacher’s task was to deliver increasingly intense shocks whenever the confederate-learner made an error in memory for the word that had been previously associated with a paired stimulus word. The confederate had been trained to make a standard series of errors. If the participant-teacher hesitated, the experimenter delivered a series of four prods, beginning with “please continue” and ending with “you have no other choice, you must go on.” The experiment was terminated if the participant-teacher refused to continue after the fourth prod.

Milgram asked forty psychiatrists from a “leading medical school” to predict the results of the study. These experts on human behavior expected that only 1.25 percent of participants would continue to the top step. In fact, Milgram found that 62.5 percent proceeded to that level. The sizable error in the psychiatrists’ predictions provides evidence that even among “experts” there is a tendency to underestimate the extent of social influence.

**Zimbardo’s Stanford Prison Experiment** One might suppose that no one could “top” Milgram’s research on obedience to authority. However, that was arguably accomplished in Philip Zimbardo’s Stanford Prison Experiment (Zimbardo et al. 1973). The participants in this study were twenty-one males between seventeen and thirty years of age who responded to a newspaper advertisement to take part in a study of prison life. Participants were randomly assigned to be either prison guards or prisoners. Zimbardo and colleagues arranged for the prisoners to be unexpectedly arrested by local police officers, fingerprinted, and jailed. After remaining in a cell for a while, the prisoner’s were blindfolded, taken to a mock jail (actually the basement of the Stanford psychology building), “stripped naked, skin-searched, deloused and issued a uniform, bedding, soap and towel” (Zimbardo et al. 1973, p. 38). On the first day, the guards began the routine of having the prisoners line up, cite the prison rules, and repeat their individual ID numbers. On the second day, the prisoners rebelled but the rebellion was put down harshly by the guards, who first called in other guard shifts for reinforcement. On subsequent days, the cruelty and abusive-ness of the guards intensified, and the prisoners became increasingly passive and demoralized. Not all guards acted the same way. Some were cruel and some were not, but the “good” guards did nothing to protect the prisoners from the cruel guards. Likewise, not all prisoners acted, or reacted, in the same way. On progressive days, five of the prisoners had emotional breakdowns requiring that they be released. The experiment was terminated after six of the originally planned fourteen days.

In this experiment, the social influence came not from the experimenter, as in the Milgram experiment, but was a dynamic consequence of the interaction between two groups and the learned roles associated with these groups. Following this most dramatic demonstration of social influence, there have been no further attempts at even more dramatic demonstrations of social influence, and, primarily for ethical reasons, there have been no further experimental studies of a prison-like environment.

**A CLASSIC FIELD-NONEXPERIMENTAL STUDY—NEWCOMB’S BENNINGTON STUDY**

One field-nonexperimental study that has, quite deservedly, received wide attention is Theodore M. Newcomb’s (1943, 1958) research on Bennington College students and subsequent follow-ups of those students (Newcomb et al. 1967; Alwin et al. 1991). Newcomb collected the initial data in 1935, the first year in which the then new Bennington College had a senior class, and data collection was continued until 1939. Since the student body was small, approximately 250 women, it was possible to collect data from almost all of the students and to follow the initial freshman in 1935 until they were seniors in 1939. An important circumstance was that the college was physically isolated and relatively self-sufficient. Tuition was high and the majority of the students came from wealthy families with conservative social attitudes. On the other hand, the faculty was relatively liberal and “felt that its educational duties included the familiarizing of an oversheltered student body with the implications of a depression-torn America and a war-threatened world” (Newcomb 1958, p. 421).

Data collected from most of the students, and in-depth interviews with a subsample of them, indicated that there was an increasing trend toward liberalism with each additional year in college. A questionnaire assessing various social and economic issues (e.g., public relief and the right of labor to organize) revealed a consistent trend toward liberalism. A straw vote in the 1936 presidential campaign indicated that 62 percent of Bennington’s freshman favored the Republican candidate (Alfred Landon), while only 15 percent of the juniors and seniors did so. Consistent with this difference, 29 percent of freshman favored the Democrat candidate (Franklin D. Roosevelt), while 54 percent of the juniors and seniors did so. An even greater ratio of difference occurred for the Socialist and Communist candidates; this varied from 9 percent for the freshman to 30 percent for the juniors and seniors. In observing changes from the freshman to the senior year, Newcomb documented changes toward liberalism that were particularly marked among the more popular students. Newcomb interpreted his results as indicating that...
the Bennington College community became a positive reference group for most of the students.

Newcomb’s initial data are striking, but the profound effect of social influence was made more obvious by the results of two follow-up studies. Interview data from the first follow-up study (reported in Newcomb et al. 1967) were collected from 1959 to 1960 when the women were in their mid-forties. The results indicated that over the twenty to twenty-five year period, most of the women had retained their liberal political attitudes. Newcomb and colleagues pointed out that the persistence of these liberal attitudes might be partially explained by the fact that they had married men with similar liberal attitudes. Data for the second follow-up study were collected in 1984, the year of Newcomb’s death, when the women were sixty-five to seventy years old (Alwin et al. 1991). Interviews were conducted with 335 of the original sample of 527 women. Most of the interviews were conducted by telephone, but twenty-eight of the interviews were conducted in three-hour, face-to-face sessions. The results indicated that 70 percent identified themselves as “liberal” and agreed with the positions of the 1984 Democrat presidential candidate, Walter Mondale, on such issues as the responsibility of government to improve the social positions of African Americans and other minorities. The women furthermore confirmed that their attitudes had grown more liberal while they were at Bennington.

The persistence of acquired liberal attitudes over an approximately fifty-year period provides strong evidence for the potentially profound effect of social influence. The Bennington study and the follow-up interviews make clear that social influence is not restricted to short-term judgments or behaviors (for example, judgments regarding which line is longer), but can be life changing.

**DEUTSCH AND GERARD ON NORMATIVE AND INFORMATIONAL SOCIAL INFLUENCE**

Morton Deutsch and Harold Gerard are widely referenced for interpreting social influence as due to two factors: normative social influence and informational social influence. They define normative influence as “influence to conform to the positive expectations of another” (Deutsch and Gerard 1955, p. 629). The idea is that agreement with another person, another group, or even the self (in the case of internalized norms) leads to expectations of positive feelings. For conformity to internalized norms (and resistance to the influence of others), they add another process. This is that such conformity “leads to feelings of self-esteem or self-approval” (p. 630). As speculated below, acceptance of the influence of others may also be related to self-esteem.

Deutsch and Gerard define informational influence as “influence to accept information obtained from another as evidence about reality” (Deutsch and Gerard 1955, p. 629). They rely on Leon Festinger’s (1950) argument that “where no physical reality basis exists for the establishment of the validity of one’s belief, one is dependent upon social reality (i.e., upon the belief of others)” (Deutsch and Gerard 1955, p. 630). Following his 1950 article, Festinger (1954) elaborated his basic argument into a theory—social comparison theory—which became one of the more influential theories in social psychology. The theory assumes that we have a drive to evaluate our beliefs in terms of their correctness or validity. The validity of our beliefs can sometimes be determined through simple observation, but, when this cannot be done—and only when this cannot be done—we evaluate the validity of our beliefs through social comparison with the beliefs of others.

The idea that the beliefs of others are a source of information determining social influence has become very influential. However, one could argue that even social comparison theory underestimates the informational value of social influence. For example, a dramatic study by Bibb Latané and John Darley (1970) demonstrated that the assumed danger indicated by an increasing amount of smoke pouring into a room was influenced by the number of seemingly unconcerned others. The greater the number of unresponsive others—actually confederates of the experimenter—the longer it took for the single participant to leave the room. This experiment provides a clear example of how, contrary to social comparison theory, social influence can alter even the judgments of physical reality.

Despite the fact that Deutsch and Gerard speculated about both informational social influence and normative social influence, their research primarily focused on normative social influence. As in Asch’s research, Deutsch and Gerard had participants and confederates make length-of-line judgments. They made a number of comparisons among their various conditions, but two of these bear most directly on the influence of group norms. One comparison was between a condition in which the groups were told that each member of the five (out of twenty) groups that made the fewest errors would receive a pair of tickets to a Broadway play versus a condition in which there was no mention of competition among the groups. There was more conformity in the former, competitive condition—presumably because the competition increased the anticipated positive feelings resulting from conformity to the group norm.

The second comparison was between a condition in which the participant (and the confederates) responded publicly, and a condition in which the participant (but
not the confederates) responded privately on sheets of paper that were subsequently discarded. There was more conformity in the former, public condition—presumably because only with public responding could the participant’s feelings be influenced by the anticipated reactions of the group members.

What about evidence for informational social influence? Deutsch and Gerard provide no evidence directly bearing on informational social influence, but they do point out that such influence is suggested by a further comparison between the private condition and a control condition in which the participants were alone. Participants made fewer errors in the direction of the group in the alone condition.

THE IMPORTANCE OF BEING RIGHT AND THE IMPORTANCE OF BEING LIKED
Chester Insko and colleagues (Insko et al. 1983; Insko et al. 1985) conducted two studies, both of which followed the Asch procedure of having a series of confederates and a single participant seated in a row of chairs, with the true participant seated next to last. Unlike in Asch’s research, the judgments were not of line lengths but of colors—for example, whether the blue-green in the middle was more like the blue on the left or the green on the right. On twelve of the eighteen trials, the confederates responded incorrectly. Both studies included two cross-cutting independent variables, thereby creating four cells or conditions. One independent vari-

able was whether the participants responded publicly or privately.

The other independent variable related to whether or not the correct answer supposedly could be accurately determined by a spectrometer. In the so-called determined condition, it was explained that a printout of the spectrometer reading would be available for examination at the end of the experiment. In the so-called undetermined condition, no printout was made available and it was explained that spectrometers could not accurately read mixed wavelengths. Assuming that the judgments of the confederates were used as a valid source of information, and assuming that participants were concerned with being right or being correct, it follows that there should have been more conformity to the confederates’ judgment in the determined than the undetermined condition.

The results indicated that there was more conformity to the confederates’ judgments when the judgments were made publicly rather than privately (regardless of whether the correct answers supposedly could or could not be determined), and there was more conformity when the correct answers supposedly could be determined rather than not determined (regardless of whether the participants responded publicly or privately). These results are consistent with expectations based on the assumed joint concerns of being right (or not being wrong) and being liked (or not being disliked). Thus, both the reduction of epistemic uncertainty and the desire to be liked seem to be factors promoting the power of social influence.

THE SOCIAL CONFORMITY DILEMMA
While social psychologists have typically studied the darker side of our dependence on social norms and collective information such as slavish conformity, destructive obedience, normative error, interpersonal cruelty, and bystander “apathy,” there are instances of the collective benefits of social influence that are abundantly evident—for example, in the acquiring of knowledge, the prevention of harmful behavior, and the coordination of activities. The fact that research on social influence has tended to focus on negative consequences should not be taken as an indication that social psychologists necessarily subscribe to the bias implicit in Western, individualistic culture that individual action and choice are always preferable to social conformity. It is obviously the case that many norms are adaptive, and that conformity to such norms, and social learning generally, can be beneficial. One of the profound dilemmas of human existence relates to when we should, or should not, conform to the behavior and judgments of others.

SOCIAL INFORMATION PROCESSING

Social information processing theory describes a set of cognitive-emotional mechanisms specifying how the way in which children interpret a particular event influences how they will respond to that situation. This framework takes into account the database of prior experiences with parents and peers that children bring to new situations. As a result of prior social interactions, children develop cognitive schemas that influence their processing of social information in new situations.

Nicki R. Crick and Kenneth A. Dodge (1994) have proposed six steps in a model of social information processing. First, encoding of external and internal cues is the process of taking in information from the environment. Second, making attributions (or interpretations and mental representations of cues) involves deciding what motivates the behavior of other people. On the basis of information children encode from a particular situation, they could decide that others acted with benign, hostile, or...
ambiguous intent. Third, selecting a goal involves deciding what the desired outcome is in a given situation. Fourth, generating responses is the process of thinking of possible behavioral actions. Fifth, evaluating responses occurs when children assess whether a response is a good one to use in a particular situation and whether that response will bring about desired outcomes. Sixth, enacting responses is the manner in which a child actually behaves.

Deficits at each of these steps have been found to be related to aggressive behavior. At the first step, aggressive children, compared to nonaggressive peers, encode a smaller number of social cues, seek additional information in ambiguous social situations less frequently, and attend selectively to hostile and threatening social cues. At the second step, aggressive children are more likely than nonaggressive children to interpret ambiguous social cues as threatening. At the third step, selecting instrumental (e.g., winning a game) rather than interpersonal (e.g., maintaining a friendship) goals is associated with behaving more aggressively. At the fourth step, generating fewer behavioral responses overall and a higher proportion of aggressive responses to problems is related to behaving more aggressively. At the fifth step, positively evaluating the likely interpersonal and instrumental outcomes of aggression is related to behaving more aggressively. At the sixth step, skill in enacting aggressive responses is related to behaving more aggressively.

Social information processing mechanisms deal with specific links among environments, cognition, and behavioral outcomes. For example, problematic parent–child and peer relationships are associated with a host of social information processing deficits. Children who have been physically maltreated, for instance, become more attentive to hostile cues in the environment and less attentive to other relevant social cues; poor encoding is, in turn, related to higher levels of subsequent aggression. Similarly, children with insecure attachments to their parents are more likely to have social information processing problems than are securely attached children; these problems appear to stem from relationship schemas involving others’ lack of emotional and instrumental availability. Children who are rejected by their peers also are more likely to have social information processing deficits that then carry over into future social and behavior problems. Thus, social information processing problems serve as cognitive mediators of the association between environmental risk factors and subsequent behavioral outcomes.

SOCIAL ISOLATION

In the social sciences, the term social isolation has two distinct usages. When applied to individuals, social isolation refers to a lack of social ties in general. When applied to social groups, social isolation refers to a lack of social and institutional ties to mainstream society. A group can be socially isolated even if the individuals within the group share a dense network of social ties with one another.

Individual social isolation is a relatively straightforward concept. It can be measured by either the percentage of the population in question that lives alone as calculated from census data or an index of social isolation constructed from survey-based social network data (e.g., the Berkman-Syme index). Given such measurements, researchers in social psychology, gerontology, public health, and many other fields have evaluated trends in social isolation and used standard methods of cross-sectional data analysis to measure the apparent effect of social isolation. This research owes much to the analysis of social isolation and schizophrenia by the Chicago school sociologist Robert E. L. Faris in the 1930s. Social isolation has been found to be a significant risk factor for many health problems and is a particular health issue for the elderly. This literature is often subject to the criticism that the simple relationship between isolation and outcomes may actually be an artifact of some unmeasured third factor (for example, alcoholism may produce both social isolation and heart disease). However, ethnographic and clinical research has also tended to support the idea that individual social isolation matters.

Group-level social isolation has been a key theoretical concept in urban sociology since the publication of William Julius Wilson’s The Truly Disadvantaged (1987), an influential study of troubled inner-city communities. Wilson argues that the limited social contact of residents with the institutions of mainstream society is the primary cause of various community social pathologies such as high rates of out-of-wedlock births, welfare dependency, school dropout, crime, and exit from the labor force. Wilson’s later work more explicitly identifies the role of high community rates of joblessness in producing social isolation. In this analysis, macroeconomic changes such as
the decline in manufacturing employment combined with the departure of the black middle class from the inner city become the underlying source of inner-city social isolation and social pathology. Wilson's focus on social isolation is distinct from those theories that trace high rates of inner-city social pathology directly to racial discrimination or individual poverty. It is also distinct from "culture of poverty" theories that argue that a substantial proportion of ghetto residents have internalized a pathological set of social values. Wilson's work has inspired a vast empirical literature on "neighborhood effects" in sociology and in other social sciences. This literature only rarely has aimed to measure group-level social isolation directly; typically it focuses on the relationship between neighborhood-level measures of poverty concentration and various individual or family outcomes.

Wilson's work has also influenced economists to incorporate social isolation into economic models of inequality. Work in this literature, surveyed by Yannis Ioannides and Linda Datcher Loury (2004), usually combines formal social network theory with microeconomic models of search and matching. Group social isolation is conceptualized here in terms of the properties of a network of connections between individuals, rather than Wilson's more holistic but difficult to quantify concept of connections between individuals and both institutions and values. One key insight from the economics literature on group social isolation is that group-level isolation, unlike individual-level isolation, is characterized by externalities. That is, a group member who takes costly effort to form social ties with mainstream society will provide benefits to other group members, and these benefits cannot be appropriated by the individual who forms the social tie. As a result, the number of social ties to the mainstream will tend to be inefficiently low.

The closely related concept of social exclusion can be considered a special case of social isolation in which blame is assigned. Brian Barry (2002) notes that "exclusion" implies that the larger society prevents social integration, whereas "isolation" in principle can be voluntary or involuntary and beneficial or malevolent. The concept of social exclusion originated in continental Europe, whereas the notion of social isolation is associated with social scientists based in the United States.

**SOCIAL JUDGMENT THEORY**

Social judgment theory was developed by psychologist Muzafer Sherif, with significant input from Carl I. Hovland and Carolyn W. Sherif. Rooted in judgment theory, which is concerned with the discrimination and categorization of stimuli, it attempts to explain how attitudes are expressed, judged, and modified. The theory details how attitudes are cognitively represented, the psychological processes involved in assessing persuasive communications, and the conditions under which communicated attitudes are either accepted or rejected. It offers a commonsense plan for inducing attitude change in the real world.

There are five basic principles in social judgment theory. The first asserts that people have categories of judgment with which they evaluate incoming information. When an individual encounters a situation in which he or she must make a judgment, a range of possible positions can be taken in response. For example, if an individual is asked to make a monetary contribution to a charity, the possible positions range from "absolutely not" to "most certainly." Along this inclusive continuum there are categories of positions that an individual may find acceptable or unacceptable, and also a range for which no significant opinion is held. These ranges are referred to as the *latitude of acceptance*, the *latitude of rejection*, and the *latitude of noncommitment*, respectively. An individual's most preferred position, located within the latitude of acceptance, is referred to as the *anchor*.

The second principle states that as people evaluate incoming information, they determine the category of judgment, or latitude, to which it belongs. In the above-mentioned example, individuals with a favorable view of the charitable cause would most likely place the request for a donation within the latitude of acceptance. Conversely, those who hold an unfavorable view of the charitable cause will locate their attitude within the latitude of rejection. Those with no significant opinion either way will locate it in the latitude of noncommitment.

The third principle asserts that the size of the latitudes is determined by the level of personal involvement,
or ego-involvement, one has in the issue at hand. People may or may not have opinions regarding the communicated information, and this will affect whether or not the persuasive message is accepted or rejected. These same opinions (or their lack) also affect the size of latitudes. The higher the level of ego-involvement, the larger the latitude of rejection becomes. For instance, an individual who is solicited for a donation to a cancer society will have a smaller latitude of acceptance if his or her mother suffers from cancer, as compared to someone who has no personal connection to the malady. For that individual, contributing to the charity is imperative, and any other response is unacceptable. Therefore, the latitude of acceptance and noncommitment will be small compared to the latitude of rejection.

Principle four states that people distort incoming information to fit their categories of judgment. When presented with a persuasive message that falls within the latitude of acceptance, and is close to the individual's anchor, people will assimilate the new position. That is, they will perceive the new position to be closer to their attitude than it actually is. When the persuasive message is relatively far from the anchor, however, people tend to contrast the new position to their own, making it seem even more different than it actually is. In both cases, individuals distort incoming information relative to their anchor.

These distortions influence the persuasiveness of the incoming message. If the message is too close to the anchor, assimilation will occur and it will be construed to be no different than the original position. If contrast occurs, the message will be construed to be unacceptable and subsequently rejected. In both cases, social judgment theory would predict that attitude change is unlikely to occur.

The fifth principle asserts that optimal persuasion occurs when the discrepancies between the anchor and the advocated position are small to moderate. In such cases, assimilation or contrasting will not occur, allowing for consideration of the communicated message. Under these conditions, attitude change is possible.

A major implication of social judgment theory is that persuasion is difficult to accomplish. Successful persuasive messages are those that are targeted to the receiver's latitude of acceptance and discrepant from the anchor position, so that the incoming information cannot be assimilated or contrasted. The receiver's ego-involvement must also be taken into consideration. This suggests that even successful attempts at persuasion will yield small changes in attitude.

**SOCIAL LEARNING PERSPECTIVE**
From the 1930s through the 1950s the behavioral theory of operant conditioning, with its emphasis on the application of consequences to influence behavioral change, was the dominant perspective in U.S. psychology. With the reintroduction of a cognitive perspective in the 1950s (e.g., Miller 1956; Miller, Galanter, and Pribram 1960), researchers began to look for ways to integrate the behavioral and cognitive perspectives. Social learning theory, as developed by Neal Miller and John Dollard (1941), Robert Sears (1951), and Albert Bandura (1977), contributed to connecting behavioral and cognitive approaches to learning and is an important step toward modern versions of learning theory.

Bandura (1962), building on the earlier work of Miller and Dollard (1941), proposed that learning first occurs cognitively through imitation and then is modified through the application of consequences. In contrast to a purely behavioral approach, social cognitive theorists propose that individuals are active participants in their own learning. Based on a series of studies during the 1960s and 1970s (e.g., Bandura 1963, 1965a), Bandura in 1977 proposed a four-step process for how individuals learn through observing others’ behavior. This process has been referred to as observational learning, or modeling, and involves:

- attention—the individual notices something in the environment;
- retention—the individual remembers what was noticed;
reproduction—the individual produces an action that is a copy of what was noticed; motivation—the environment delivers a consequence that changes the probability that the behavior will occur again (reinforcement and punishment).

Through the careful observation of others, individuals learn numerous new behaviors such as emotional reactions and how to use tools in their environments. Bandura (1965b) demonstrated that individuals modify their own behaviors based on the consequences (e.g., reinforcement or punishment) that others receive. He called this phenomenon vicarious learning. Individuals tend to model their behavior on persons who are similar to themselves, persons who are of higher status than themselves, and persons who are either reinforced for their behavior or not punished for it. One example of the power of imitation is found in the results of the infamous “Bobo doll study” (Bandura, Ross, and Ross 1961). In this study preschool children who observed adults mistreating a Bobo doll were more likely to engage in similar aggressive behavior than children who had not observed the adults’ aggressive behavior.

In more recent years, Bandura turned his attention to the importance of self-efficacy, self-regulation, and the desire of individuals to develop agency over their lives (Bandura 1986, 1989, 2001). To describe the learning process from this perspective, Bandura developed a concept called reciprocal determinism, which details a three-way relationship between a person, his or her behavior, and the environment. In the social-cognitive model each of the three elements are equally important and influence the other elements. Thus, an individual’s unique characteristics interact with overt behaviors and environmental models and feedback.

**SOCIAL MOVEMENTS**

A social movement can be defined as a collectivity with mutual awareness in sustained interaction with economic and political elites seeking to forward or halt social change. Social movements are usually comprised of groups outside of institutional power that use nonconventional strategies (e.g., street marches, sit-ins, dramatic media events) along with more conventional ones (e.g., petitions, letter-writing campaigns, etc.) to pursue their aims (Tarrow 1998; Snow et al. 2004). The outsider status and nonconventional tactics of social movements distinguish them from other political entities such as lobbying organizations and political parties (though these more formal organizations may originate from social movements). Most people participate in movements as volunteers and offer their time, skills, and other human resources to maintaining movement survival or achieving goals. Examples of social movements range from community-based environmental movements to transnationally organized economic-justice movements.
attempting to place pressure on national governments and international financial institutions. The modern social-movement form arose with the spread of parliamentary political systems and nationally integrated capitalist economies in the nineteenth century (Tilly 2004).

EMERGENCE

Social movements are most likely to arise when a particular collectivity comes under threat or receives signals from the political environment that advantages may be forthcoming if groups decide to mobilize. In other words, either “bad news” or “good news” may motivate episodes of collective action (Meyer 2002). Under bad-news conditions, a community or population perceives that its situation will become worse if it fails to act and that it may lose collective goods (e.g., loss of land, rights, employment, etc.). In the good-news political environment, groups sense that they will acquire new collective goods if they act in concert (e.g., new rights, higher wages, greater environmental quality, etc.). Often, bad-news and good-news protest campaigns are triggered by government policies that signal to would-be challengers that the state is becoming less or more receptive to the issues that are most meaningful to the population in question.

Besides these motivations for movement emergence, some type of organizational base needs to be in existence to mobilize large numbers of people (McAdam 1999). These organizational assets may be traditional, such as solidarities based on village, religious, regional, or ethnic identities, or they may be associational, rooted in secondary groups such as labor unions, social clubs, agricultural cooperatives, educational institutions, and more formal social-movement organizations (SMOs) (Oberschall 1973). Without preexisting solidarity ties and organizational links, either formal or informal, it is unlikely that threats or opportunities will convert into social-movement campaigns. Hence, social-movement scholars give special attention to variations in organizational resources across localities and over time in explaining social-movement emergence (Edwards and McCarthy 2004).

OUTCOMES

Perhaps the most important social-movement arena involves movement impacts. That is, what kinds of changes in the political environment can be attributed to the existence and actions of a social movement? What aspects of social change can be explicitly associated with the activities of a movement? Students of social movements examine various aspects of social-movement outcomes. The enduring changes associated with movements include the impacts on movement participants, changes in the political culture, influence on state policies, and “spillover” into other social movements (Meyer and Whittier 1994). In comparison to movement emergence, there is less scholarly consensus on social-movement outcomes (Jenkins and Form 2005). Often, it is difficult to decipher the particular contribution of a social movement to a specific outcome while attempting to control for non-movement influences. Despite these scientific shortcomings, major movements of oppressed social groups in the United States greatly improved their social standing. Participants of such movements obtained major policy changes because they engaged in social-movement-type struggles, especially the women’s movement and the African American civil rights movement in the late twentieth century.

A classic study on movement outcomes by William Gamson (1990) found in a representative sample of fifty-three voluntary associations in the United States between 1800 and 1945 that groups that maintained single-issue demands, used more assertive strategies and tactics, and organized themselves along more bureaucratic lines were more successful in achieving their goals than movements that lacked these properties. In terms of state-oriented social movements, or movements with political aims that largely target the government, linking with sympathetic groups inside the state enhances probabilities of movement success (Banaszak 2005). For example, a 2004 study of national environmental politics in Japan by Linda Brewster Stearns and Paul Almeida found that antipollution movements were much more successful in winning new environmental policies when they formed loose alliances with actors inside the government, such as city councils, sympathetic federal agencies, oppositional political parties, and the courts.

THEORIES OF SOCIAL MOVEMENTS

Between the 1960s and the 1980s, a clear succession of social-movement theories took shape—from collective behavior to resource mobilization to political-process perspectives. Since the mid-1990s, social-movement scholarship places much more emphasis on a synthetic approach that combines resource mobilization, political opportunity, and framing perspectives into a larger comprehensive framework of social-movement dynamics. Individual scholars, though, still tend to specialize in one of the three subareas of this larger synthesis.

Resource mobilization scholarship emphasizes the role of formal and informal organizations in collective action. Resource mobilization scholars also attempt to define the population of SMOs within movements and societies using such terms as social-movement sector, social-movement industry, and organizational field (McAdam and Zald 1977; McAdam and Scott 2005; Minkoff and McCarthy 2005). More recent work in the resource mobi-
Social Movements

The political-process tradition centers on the larger political environment and how differentially configured political contexts shape social-movement emergence, forms of mobilization, and movement outcomes. Important features of the political environment are referred to as political opportunities. Five key dimensions of political opportunity shaping collective action within political-process theory include:

1. institution access (i.e., the opening of state agencies)
2. elite conflict (between political or economic elites)
3. electoral realignments (i.e., changing electoral coalitions)
4. influential allies (i.e., experts, mass media, religious institutions, etc.)
5. a relaxation in state repression.

The more these five elements of opportunity are present in a political environment, the greater the probability of the emergence of a large and efficacious social movement. Some versions of political-process theory contend, however, that high levels of political opportunity lead to more institutional forms of politics and less need for social-movement mobilization (Eisinger 1973; McAdam 1996; Meyer 2004; Tarrow 1998).

The framing perspective derives from the interpretive tradition in sociology with a special concern for how activists construct social grievances. It is now largely understood that injustice and organizational resources alone do not explain the timing and location of social-movement-type mobilization. Movement leaders and activists must construct norm violations, grievances, and experiences of oppression and injustice in socially meaningful and convincing ways that will motivate the targeted populations to participate in collective action (Snow et al. 1986; Snow and Benford 1988). In other words, social and political activists must “frame” the social world in such a manner that it resonates with rank-and-file movement supporters as well as sympathizers and fence-sitters.

Students of social movements often discuss the ability of political movements to develop collective-action frames that will generate large-scale support for the challengers’ objectives. The collective-action frame of “civil rights” in the African American freedom struggle in the 1950s and 1960s is considered a particularly potent frame consonant with the political culture and values of the United States, bringing in large numbers of white Americans in solidarity with the grievances of black Americans. In addition, the success of the “civil rights” frame led to several other movements adopting a variant version in subsequent decades. Such movements include the women’s, gay/bisexual, Mexican American, Asian American, and disability movements, as well as more conservative movements, such as the pro-life, home schooling, or pro-creationism movements, which invoke civil rights in their claims-making activities.

One avenue for categorically deciphering collective-actions frames is to divide them into their diagnostic, prognostic, and motivational functions. A diagnostic frame defines particular social problems and injustices and assigns blame to the agent(s). Prognostic framing develops an action plan to resolve the social problem or grievance, while motivational framing includes the actual mobilization appeals to persuade people to join the movement or participate in a particular action. David Snow and Robert Benford (1988) view these three core framing tasks as a fundamental part of sustaining social-movement mobilization.

RECRUITMENT

Social-movement recruitment and individual-level participation draw on microlevel models of collective action. Early explanations of social-movement recruitment and participation emphasized the irrationality aspects of mass movements. Political movements of the unruly were viewed as fulfilling psychological deficits for movement participants—a kind of therapy to overcome sentiments of alienation and social strain inherent in fast-paced industrialized urban societies (McAdam 1982). By the late 1970s and early 1980s, scholars began to look at more than just the beliefs and psychological profiles of movement participants. They also examined the microstructural context of mobilization, namely the social ties and networks of potential movement recruits (Snow et al. 1980; McAdam 1986). This newer empirical research found that movement participants were often highly socially integrated in their everyday lives and more likely to belong to civil society associations and clubs than those who did not participate in social movements. In addition, the connections individuals maintained with movement sympathetic organizations and individuals made them much more likely to join a protest campaign, whereas those connected to organizations and individuals opposed to such activities were much more likely not to participate (McAdam 1986). Finally, movement mobilization occurs at a faster rate when entire groups and organizations are recruited en masse as opposed to organizing single individuals one at a time—a process termed bloc recruitment (Oberschall 1973).
Movement-recruitment research also distinguishes between low cost/low risk activism versus high cost/high risk activism (McAdam 1986). Cost refers to the time and resources put into a particular movement campaign. Risk involves the level of personal harm that may result from activism (e.g., reputation, imprisonment, physical safety). For high cost/high risk activism, such as occurs in extremely oppressive regions or societies (e.g., a racially segmented society, a military dictatorship, etc.), a deeper level of integration into a social-movement culture by the individual needs to take place, including previous participation in several rounds of low cost/low risk activism.

NONDEMOCRACIES AND STATE REPRESSION

The majority of social-movement studies focus on movements in industrialized democracies in the global north (McAdam et al. 1996). However, a growing body of literature now exists for political contexts outside of the democratic West. The more stable forms of government in Western democracies allow for a greater upkeep of social-movement-type organizations and more space to launch largely nonviolent campaigns. In nondemocratic and quasi-democratic nations (e.g., monarchies, dictatorships, military juntas), where associational freedoms are proscribed and regular multiparty elections do not occur, scholars face challenges in explaining when social movements will arise and what forms they will take. One fruitful avenue investigates “cracks in the system,” small political openings, or larger moves toward political liberalization in nondemocracies. These conditions often provide a conducive environment for a few entrepreneurs in civil society to attempt to form civic associations and possibly even begin to seek small reforms. Other movements may be launched in institutions outside the purview of state control, such as religious institutions (mosques, religious schools, Catholic youth groups, etc.) or remote territories not completely controlled by the administrative state apparatus and army. Foreign governments and movements may also support a fledgling movement in a nondemocratic context.

In the twentieth century, nondemocratic countries were much more likely to experience a radical revolutionary challenge from below than democratic states (Goodwin 2001). Revolutionary movements can be seen as a special type of social movement that seeks the overthrow of the government as its central goal, rather than piecemeal policy change. Oftentimes, revolutionary movements begin as reformist movements during a period of regime liberalization and only radicalize once the regime closes down the reform process. The violent repression of reform-minded groups transforms popular conceptions of the entire political system and provides incentives for the formation of more radical and revolutionary political organizations. Such a scenario developed in El Salvador during the 1960s and 1970s, as well as in Guatemala in the 1950s and 1960s, and more recently in Algeria and Nepal.

CONSERVATIVE MOVEMENTS

In the United States, conservative social movements have been on the rise since the 1980s. The emergence of an evangelical protestant Christian Right in alliance with the Republican Party has provided a favorable political context for conservative movements that seek to halt certain social policies perceived as morally reprehensible (e.g., same-sex marriage, legalized abortion, secularism in public schools, etc.). The movement’s success resides in its capacity to form coalitions with different levels of government and to employ bloc recruitment strategies (e.g., mobilizing entire church congregations). Since the early 1990s, the Christian Right has won seats in hundreds of school boards, city councils, and state and national legislatures. The movement has also influenced the selection of Supreme Court justices (Micklethwait and Wooldridge 2004). In the 1990s and early 2000s, researchers found that extremist right-wing activity in the form of hate crimes and paramilitary militia groups in the United States was associated with job loss, economic restructuring, and lack of contact between educated and less-educated populations in the regions where these movements arise (Van Dyke and Soule 2002; McVeigh 2004).

TRANSNATIONAL SOCIAL MOVEMENTS

A major area of research involves the expansion of transnational social movements that link members and organizations across more than one country. Two noteworthy transnational movements in the early twenty-first century include international Islamic solidarity and the global justice movement. Internationally connected Islamic movements benefit from the concept of umma—the larger community of believers that links the Muslim world beyond national borders (Lubeck 2000). With global migration flows and new communications technology, Islamic-based social movements easily mobilize internationally. Early signs of this emerging process occurred in the 1980s during the Afghan-Soviet war. Thousands of Muslims and Arabs traveled from dozens of countries in the Middle East, North Africa, and beyond to Afghanistan to fight in a jihad (holy war) as the mujahideen (guerrilla fighters) against the secular Soviet Union, which invaded the country in 1979. The foreign Islamic fighters felt an international sense of solidarity with their fellow Muslim Afghans suffering under Soviet occupation. This struggle served as the base of the Al-Qaeda movement, which built a large multinational net-
work out of the social contacts made in Afghanistan. This network of transnational Islamic insurgents has since been used to send foreign contingents to wars in Bosnia, Chechnya, Iraq, Somalia, and other places.

The global justice movement (sometimes referred to by critics as the antiglobalization movement) is another major transnational movement that emerged in the late twentieth century. Supporters of this movement use global communications technologies to mobilize constituents. The global justice movement arose almost simultaneously with the expansion of the global Internet infrastructure between the mid-1990s and the early 2000s. Several organizations in Europe and Canada, including the Council of Canadians, Jubilee 2000, People’s Global Action, and ATTAC, began to work with nongovernmental organizations in the developing world to place pressure on newly emerging and older transnational governing bodies and economic institutions such as the United Nations, the World Trade Organization (WTO), the International Monetary Fund, the World Bank, the Group of Eight (G8), and the European Union.

The demands of the global justice movement vary but tend to focus on third world economic justice, environmental protection, and the need for more transparency in decision making among the elite transnational economic and political institutions mentioned above. Though the movement held several major protests in the late 1990s outside of WTO and G8 meetings in Europe, a massive demonstration at the 1999 WTO meetings in Seattle, Washington, served as a breakthrough for the global justice movement. It was the largest sustained protest in an American city in several decades (Almeida and Lichbach 2003). Global justice activists coordinated the arrival of participants around the country and world via the Internet and organized the protests in the streets of Seattle with cell phones. Dozens of countries across the globe also experienced protests in solidarity with the actions in Seattle. The success of the Seattle mobilizations provided a template for organizing dozens of similar global days of action during major international financial conferences or free trade meetings in the first years of the twenty-first century.

BIBLIOGRAPHY

Social Psychology

Social psychology is the scientific study of how people think about, influence, and relate to one another. By studying social thinking, social psychologists examine how, and how accurately, we view ourselves and others. By studying social influence, social psychologists examine subtle forces related to conformity, persuasion, and group influence that pull our strings. By studying social relations, social psychologists examine what leads people to hate and hurt one another, or to love and help one another.

Social psychology as a field lies between personality psychology and sociology. Metaphorically speaking, personality psychologists study boats, sociologists study the ocean, and social psychologists study how those boats float. When a person (boat) arrives in an environment (ocean), social psychologists want to understand how they move on the winds and currents.

Social psychology considers many of the same questions as those sociology considers but favors answers that focus on the individual actors (such as the way they perceive their situations) rather than on answers that apply to the group level (such as poverty or family cohesion). It is also distinct from personality psychology, being less interested in individual differences (such as in aggressiveness or unhappiness), though it often considers individual differences that interact with situations (such as when a person with high self-esteem responds to a relationship threat by liking his or her partner more).

Compared to other social sciences, social psychology has few grand theories or revered old masters; it has no Freud or Durkheim. Instead it interweaves smaller, more focused studies that cover topics as diverse as the self, culture, persuasion, group dynamics, prejudice, and eyewitness identification. Despite its enormous scope, social psychology has several themes running through it, including:

• We construct our social reality
• Our social intuitions are often powerful but sometimes perilous
• Social influences shape our behavior
• Personal attitudes and dispositions also shape behavior
• Social behavior is also biological behavior
• Social psychology’s principles are applicable in everyday life

As practiced in North America, social psychology is overwhelmingly experimental. It has also exhibited a willingness to engage social issues such as prejudice, violence, and public health.
HISTORY

Norman Triplett’s 1898 experiments are generally regarded as the first social psychological studies. He showed that people would wind reels faster when others were present, an effect now referred to as social facilitation. Social psychology remained a small field until World War II, at which point the U.S. Army’s sudden interest in personnel selection and stress responses led it to sponsor some highly innovative work. In the decade after the war the field exploded: Gordon Allport wrote an enormously influential book called The Nature of Prejudice (1954), Solomon Asch (1951) conducted experiments on conformity, Stanley Milgram (1974) conducted his famous experiments inducing people to give supposedly powerful electric shocks to a mild-mannered man, and Leon Festinger (1957) proposed his influential cognitive dissonance theory.

In the last quarter of the twentieth century, social psychology was dominated by a cognitive perspective that asked how we process social information. During the 1990s and beyond, it also has had a growing interest in “warmer” motivational processes and broad cultural influences.

METHODS AND ETHICS

Modern social psychology favors experimental research, with many published articles describing two to seven experiments or quasi-experiments that explore and refine some central idea. Correlational studies are also used, but often given short shrift in favor of experimental evidence. The field also puts great stock in meta-analyses that combine many previous empirical studies. Experiments use diverse manipulations, ranging from the subliminal presentation of words, to interaction with confederates, to false feedback on IQ tests.

Social psychological research is now subject to oversight by institutional review boards that safeguard ethical standards. While these are widely regarded as necessary in light of the ethical controversies that centered on some prominent early studies, social psychological experiments are almost never, in any real sense, hazardous.

PARTS OF THE SOCIAL MIND

Psychologists separate affect (emotions), from behavior, from cognition (thoughts), then study how they interact. Affect has broad consequences. People who are in a good mood tolerate more frustration, choose long-term rewards over immediate small payoffs, and see others in a more optimistic light. A growing movement in psychology known as positive psychology focuses specifically on well-being and how it can be enhanced.

Attitudes, in social psychological parlance, are the affect people bear toward some object or activity. Social psychologists study how attitudes form and change, how strong and durable they are, and how much they predict actual behavior. The answer to the latter question, under many circumstances, is “somewhat, but not as much as you might think.”

Since the 1980s cognition has increasingly become a focal point for social psychologists. They study when cognitions are activated (come to mind), how they are organized into schemas, and when people are motivated to think things through systematically as opposed to using heuristic mental shortcuts. Some influential models, such as the theory of reasoned action, describe how a person’s beliefs about an object (“it’s big, loud, and emits black smoke”) are combined to produce an overall attitude (“I hate it”).

Affect and cognitions influence behavior, but behavior can also influence affect and cognition. Under the right conditions, both saying and doing can lead to belief (if you say that you like something enough, or just keep buying it, and you might really end up liking it). Even just arranging your face muscles into the shape of a smile can make you feel happier.

Although affect, behavior, and cognition are social psychologists’ central organizing principles, other parts of the mind have also been of interest, such as memory and physiological arousal. The self is an enormous area of study, encompassing thoughts about who one is (self-concept or identity) and attitudes toward oneself (self-esteem).

People organize knowledge about themselves into well-integrated pictures, or self schemas, that help them quickly sift and sort the world. People better remember things that are relevant to their self schema, and spontaneously make social comparisons between themselves and others. Self-serving biases describe the ways we distort the world to make ourselves look better (for example, by taking more responsibility for our successes than our failures). Self-monitoring describes people’s tendency to engage in impression management—altering their social identity to fit different roles in different places (friend at school, son at home, employee at the office). Manipulations that affect people’s self-awareness (the presence of mirrors, seeing one’s own name) encourage people to act more in line with their stated attitudes.

DYNAMICS OF THE SOCIAL MIND

Scholars have devoted much attention to social influence—the ways in which individuals and groups come to change others’ thinking or behavior. Early dramatic studies showed that people seemed remarkably vulnerable to social influence. In Asch’s famous experiment, they doubted their own eyes when others claimed to see things
that were patently untrue, and in Milgram’s experiment, they gave extremely painful electrical shocks on command. People can, however, resist social influence. Even in these seminal studies compliance was far from universal, and rates of conformity were rapidly deflated by small changes, such as a lack of unanimity among influencers and a greater distance from authority figures. Much work has gone into who conforms to what, when, and why, with several important factors identified in the study of persuasion. These include who (attractive person, authority figure) says what (reasoned vs. emotional message, one- or two-sided appeals) to whom (audience pays close attention or not).

In the 1990s social psychologists started directing their attention more towards “warm” or motivated cognition—people’s attempts to arrive at the answers they would like to. People bring this convenient brand of reasoning to many tasks, including forming impressions of themselves and others, attributing motives for actions, and judging the desirability of various outcomes. They do this, though, with some constraints imposed by reality—most consider themselves more moral than average, but few claim saintliness.

Scholars have become increasingly interested in automatic processing, in which judgments, associations, or even actions are made quickly and efficiently with little conscious guidance. For example, work has focused on negative stereotypes that rapidly come to mind when people encounter minority groups. A number of “dual-process models” have been proposed for processes like impression formation, attitudes, persuasion, and stereotyping. In these models people first have a fast, efficient, automatic and uncontrolled reaction that is later adjusted, if the person is so motivated, by conscious thought. Upon seeing a stranger fall over, for example, a fast, effortless inference might be drawn that this person is clumsy. If one liked the person, however, within less than a second one might start searching more deliberately for outside factors and conclude that the person was pushed, or that the floor was slippery, overruling (at least partly) one’s initial verdict.

Attraction and intimacy form another major dynamic of interest. Liking is influenced by factors such as proximity, familiarity (the “mere exposure” effect), physical attractiveness, and the sharing of things about one’s self. One of the more prominent models of intimate relationships, Robert Sternberg’s triangular theory (1988), describes any given relationship in terms of passion (infatuation), intimacy (liking), and commitment (a desire to stick it out). Sternberg argues that a relationship may have only one of these (friends typically have intimacy but no passion), two (good friends would add commitment), or all three (which he calls “consummate love”).

When people get together, the resulting groups take on dynamics of their own. People in them work harder when their contributions are visible (social facilitation), but coast when their contributions are unidentifiable (social loafing). Group discussions also sometimes accentuate initial attitudes and actions (group polarization). Sometimes large groups of people will engage in behaviors that none of their members would have contemplated doing on their own (such as chanting for suicidal people to jump), partly because the individual members become “deindividuated”—they lose the self-awareness that anchors them to their personal standards.

APPLICATIONS

Social psychological work has been applied to a great many real-world settings. Researchers have brought it to the study of health behaviors, such as smoking and use of condoms, and in doing so have offered practical advances. They have spearheaded, for example, graphic pictures of decayed teeth and lungs on boxes of cigarettes in Canada. Political psychologists have, likewise, been interested in models of persuasion and attitude formation and change. Organizational psychologists have applied social psychological theories of group processes, satisfaction, and enjoyment to the context of the work place.

Law is another area that has seen widespread application of social psychological research. Psychological work has revealed that eyewitness identification, long a linchpin of legal evidence, is often flawed. It is often very difficult for people to accurately identify even those at whom they have had a good long look. Research has been used to improve identification lineup procedures to produce fairer results with fewer false positives, for example by instructing witnesses that the suspect may or may not be in the lineup. Social psychologists have also been involved in great controversies over the accuracy of “recovered memories”—recollections of past abuse that people believe they have rediscovered later in life. Research shows that, though some such cases may be genuine, some are almost certainly not, as it is not difficult to create false memories in people.

HOT AREAS

As brain imaging technology advances, rapid strides are being made into understanding the brain functioning associated with attitudes, emotions, and behaviors. Early attempts were sometimes dismissed as “color phrenology”—attempts to put people in a scanner and simply catalogue which areas lit up. Newer work compares the known functions of brain regions with their activation during social behaviors. For example, researchers might note that in some types of people subliminal exposure to African American faces simultaneously activates areas...
associated with alarming stimuli and areas associated with cognitive control. They might infer from this that an emotional reaction is taking place, alongside an effortful attempt to control it.

**SOCIAL RELATIONS**

Social relations are patterned human interactions that encompass relationships among individuals, informally organized groups, and formally organized groups, including the state. Modern-day approaches to social relations are represented by individualist, structuralist, and institutionalist theoretical frameworks. Exemplary thinkers have been selected in the field of labor relations and in the study of political processes to illustrate these different approaches.

Individualist theories explain social relations as the response of the rational individual to the outside environment. Individuals are assumed to be able to determine, and then act, on their personal self-interest. Thomas Malthus (1766–1834) and John Stuart Mill (1806–1873) were key figures in systematizing individualist thought. In the social sciences, particularly in economics, individualist explanations have historically exerted great influence, and since the 1960s they have enjoyed renewed popularity in political science and sociology in the form of rational choice theory.

Structuralist theories emphasize the presence of underlying structures in human relations. These structures have a systematic character, including mechanisms of self-regulation and self-transformation. Karl Marx’s theory that capitalist development is driven by a contradiction between the forces of production and the social relations of production is a prime example of a structuralist theory. The *forces of production* refer to labor processes, such as mechanization, the reorganization of the workplace, and the education of the working class. The *social relations of production* refer to the relations between capitalists, who enjoy a monopoly control over the means of production, and workers, who rely exclusively on their own labor power. When the forces of production and the relations of production get seriously out of joint, revolution occurs and leads to the creation of a new system of production with different social relations of production.

Institutionalist theories, in contrast, focus on the role of institutions possessing organization, rules, and shared goals in the shaping of social relations. Institutions are not seen as reflections of underlying structures but as at least partially autonomous units. John R. Commons (1862–1945), Karl Polanyi (1886–1964), and Thorsten Veblen (1857–1929) are among the founders of institutionalism. Long a minority current and largely confined to economics, since the 1990s a “new institutionalism” has won growing support among economists, sociologists, and political scientists.

**LABOR RELATIONS**

These different approaches can be seen in labor relations, a field to which individualists, structuralists, and institutionalists have contributed significantly. They have all been concerned with labor militancy, but each analyzes militancy in distinctive ways and poses different central questions. Individualists ask why a rational worker would join a trade union or participate in strikes. The economist Mancur Olson, in *The Logic of Collective Action* (1965), questions why workers would join a trade union when the results of collective actions are “collective goods” (defined
as goods that benefit all). These results are thus shared by all workers, whether or not they participated in the collective action. A rational worker would let others join and pay the costs of striking, while waiting to achieve any collective good their action might produce. To overcome a rational worker's objections to collective action, Olson suggests that unions often use selective incentives, or benefits confined to group members, such as the exclusion of nonunion workers from employment (closed shops), to make sure that the rewards of collective action are confined to participants in collective action. While Olson's analysis offers insights into some problems of labor relations, it conflicts with observed worker behavior. Strike-prone French and Italian workers have historically lacked benefit packages and closed shops.

In contrast to Olson's individualist focus, John Kelly's Marxist approach asks how militant collective identities are formed at the workplace. To Kelly, social relations play a big role. In *Rethinking Industrial Relations* (1998), he argues that capitalists' monopoly over the means of production enables them to exploit workers, and that workers' experiences at work give them a limited consciousness of their own exploitation. But when do workers come to see their exploitation as class injustices rather than as flaws of particular employers or the products of local circumstances? Emphasizing that consciousness emerges from the interaction of labor processes and social relations, Kelly focuses on the role of ideologically motivated activists on the workshop floor who persuade workers through talk and by collective action that their fate is inextricably bound up with that of the class collectivity. Kelly emphasizes that workers' ideologies and workplace struggles— their social relations—are as important as productive forces in the evolution of worker radicalism.

While social relations play a major role in Kelly's Marxist analysis of labor relations, structural forces also remain crucial. Kelly argues that the decline in labor militancy in the United Kingdom and much of the contemporary Western industrial world is a cyclical phenomenon produced by Kondratieff waves, which are decades-long waves of economic activity. During the upswing of Kondratieff waves, employment increases and the workers' bargaining position strengthens. The opposite occurs during downswings, however, and turning points correspond to historical changes in systems of labor organization. The contemporary decline in unionism in the private sector in the United Kingdom and many industrialized nations does not constitute a dissolution of class as much as it represents the triumph of aggressive capitalism during a favorable historical period.

Kelly's argument puts a good deal of weight on the role of radical political action within trade unions in promoting class identities, but little information is presented about what motivates activists or how militant organizations are sustained. A Kondratieff wave is a good example of a deep structure, one that exerts great influence but that may escape detection entirely by contemporaries. But Kondratieff waves are also problematic because so little is known about their causes. In addition, because the number of cycles is so small, the possibility exists that random forces are at work.

Institutionalist labor relations acknowledge both class and individualist concerns, but they focus major attention on institutional regulation, emphasizing the constructed character of social relations. Institutionalis-
ists ask why various industrialized nations possess very different systems of industrial relations. A good example of an institutionalist approach is that of Bo Rothstein, who argues that the character of unemployment insurance programs explains why Scandinavians have significantly higher union membership than other Europeans (1992). According to Rothstein, government-subsidized, union-controlled unemployment insurance programs prevail in Scandinavia, while compulsory national unemployment systems dominate elsewhere. A union-organized unemployment system, the so-called Ghent system, allows Scandinavian unionists to limit benefits to unionized workers, to decide what jobs are suitable for unemployed workers and, as a consequence, to increase labor's control over the labor supply. In Sweden, for example, the union-dominated Ghent system was implemented by Social Democrats with these ends in view. The welfare system actually promotes unionization, accounting for as much as 20 percent of Sweden's lead in unionization over major non-Scandinavian European nations.

Although individualists, structuralists, and institutionalists pose different questions about labor relations and pursue different research agenda, there is some room for common ground. Rothstein underlines the importance of the autonomous creation of Ghent system type welfare programs but also stresses that such institutions may be seen as an example of the selective incentives dear to Mancur Olson. Rothstein also adds that Marxist theories of class formation help explain why trade unionists entered politics to pursue class objectives in the first place.

### POLITICAL PROCESSES

Social relations concern not just questions of collective action but also issues of political process of concern to social scientists. Recent debates over the evolution and effects of democratization show how individualist, structuralist, and institutionalist approaches can be applied to political issues.

Many individualists emphasize the importance of reciprocity in understanding political processes, as well as the role of democratic polities in fostering norms of reciprocity. In democracies, such norms are formed in repeated
social exchanges that define appropriate behavior and promote collective benefits. Over the course of repeated interactions, individuals learn the value of cooperation and can reasonably expect that their contributions will be rewarded by others’ contributions at a later stage of the game. An application of an individualist approach to politics processes can be seen in Consent, Dissent, and Patriotism (1997), Margaret Levi’s study of conscription and conscientious objection. Levi argues that, however patriotic, rational draftees might be expected to stay home and let others bear the brunt of the battle. Patriotism makes sense when prospective conscripts can be sure that others will also answer the call. Surveying military service in six countries over extended periods of time, Levi found that young men are most likely to respond when they trust that the government is making policy and implementing it fairly, when they see that others are obeying, and when they receive information that confirms government trustworthiness and popular responsiveness. Thus, faith in government’s equity and capacity breed civic trust.

A structuralist perspective on democratization and distrust can be seen in Quintan Wiktorowicz’s book The Management of Islamic Activism (2001). Wiktorowicz studied the response of Islamic movements to Jordan’s post-1989 democratic reforms, and he shows how Islamic movements that have adopted formal organizational structures and subjected themselves to state regulation have been systematically manipulated and denied the ability to articulate independent political positions. Charitable societies, religious judges, Mosque preaching, and the Ramadan religious period are carefully policed and regulated by the Jordanian state. One important political-religious group, the Muslim Brotherhood, benefits from state largesse, encouragement, and even facilitation, and it has become a politically moderate ally of the Jordanian state. In contrast, Salafi Muslims have avoided integration and have remained informally organized. Salafi networks possess significant influence in religious education where they advocate social justice and Islamic practices that contrast with the regime’s support of the status quo. Rejecting efforts at government control, Salafis have resisted formal organization and, in the underworld of informal organization, reformist Salafis have often established contacts and have been influenced by more radical Islamic Salafis.

Wiktorowicz shows that Jordan’s allegedly democratic reforms have not produced democracy. Still, changes in state structure have not been ineffectual. Changes in state structures have profoundly affected the character not only of Jordan’s quiescent formal political organizations, but also that of the government’s rebellious, informally organized opposition.

From an institutionalist perspective scholars have also been interested in how allegedly democratic reforms can actually restrict democratic politics and undercut the agents of state capacity. Ezra Suleiman’s book Dismantling Democratic States (1997) is a “new institutionalist” study of governmental deregulation and de-democratization in some important industrial nations. Suleiman suggests that debates over governmental reform changed in the 1980s and 1990s. During these decades, encouraged by advocates of a “New Public Management” policy, attacks on bureaucratization no longer focused on creating a more efficient public civil service but on championing a privatization that, Suleiman believes, weakens democracy. Privatization, he argues, necessarily destroys the public space in which contemporaries can debate political options, while broadsides against bureaucratization undermine faith in the civil servants and governmental institutions that represent the most practical civic alternative to markets. At the higher levels of government, there is increasingly little place for the career civil servant, while business experience is taken as a desirable and sufficient qualification for those charged with serving the public good. But if states no longer foster institutions that possess autonomous power, why debate politics at all? When consumers replace citizens, political authority and democratic politics necessarily contract.

In the case of political processes, as in that of collective action, individualist, structuralist, and institutionalist theories all offer valuable insights. Levi’s study of conscription shows how democratic governments can build trust by creating institutions that treat citizens equally and that are sufficiently transparent to let citizens see they are being treated fairly. Wiktorowicz’s study of political integration in Jordan shows what happens when state administration is inequitable and when it denies equal treatment to political groups, bringing some into the government and condemning dissenters to the murky world of informal organization and secrecy. Finally, Suleiman demonstrates the growing danger of replacing democratic institutions with markets. Such a situation provides little room for citizens to engage in the kind of debate and civic interaction that Levi argues builds trust, and it provides no vehicles for integrating dissent into the political order.

In conclusion, a look at individualist, structuralist, and institutionalist theories shows a clear difference in their central organizing questions and their root conception of fundamental social relations. Yet each offers valuable insight into important aspects of collective action and political process. The current challenge seems to be not so much to dismiss or discard theories, but to look for new ways to integrate significant contending theories.

SOCIAL SCIENCE

An eclectic and sometimes polarizing term, social science is a broad umbrella linking multiple fields, with contention regarding which fields should be included under its purview. Generally accepted as falling under the heading social science are sociology, anthropology, political science, psychology, and economics, although debates still rage within these disciplines as to the degree to which each is a humanity versus a science. Disciplines such as history and linguistics, while still addressing social life, are less often included as social sciences. In general, social science can be regarded as the scientific method’s application to all things social. It should be noted, however, that most social sciences manifest, to a greater or lesser degree, a humanities emphasis as well as a scientific one.

There is still some debate regarding the use of the term social science, with criticism generally aimed at the word science. Traditionally, the natural sciences, or “hard sciences,” have been characterized by the use of the scientific method, which involves generating testable hypotheses in order to predict future outcomes and the ability to falsify these hypotheses. When applied to the natural world, the scientific method allows for high degrees of predictability, due to science’s ability to recognize and understand universal laws governing empirical reality. When applied to the social world, however, comparable levels of prediction and discoveries of analogous universal laws governing human behavior have proven to be more allusive. Due to the social sciences’ limited success in employing the scientific method, they are often referred to as the “soft sciences.”

ORIGINS

No definitive date can be given for the birth of social science—its emergence is in fact due to a large number of circumstances spanning centuries and some of its rudimentary ideas can be traced to multiple origins, some dating as far back as Plato. It is generally accepted that an important era in the emergence of contemporary social science began with the Enlightenment and its emphasis on rationality, logic, and methodology as applied to the empirical world. There are scholars, however, such as Lynn McDonald, who contend that the foundation of social science should be traced back to the sixth century (McDonald 1993). Maurice Duverger (1961) has argued that the social sciences, despite early roots in Grecian inquiries into the nature of man, did not emerge as a distinct form of research until the eighteenth century, when social philosophy bearing a “philosophical attitude” gave way to a new scientific emphasis. This shift from social philosophy to social science was given impetus by the emergence of positivism as a widely accepted mode of knowledge. First articulated by August Comte and best described in his 1848 work A General View of Positivism, positivism moved almost entirely away from metaphysical speculation and instead focused on the scientific method’s ability to produce facts and falsifiable statements about the empirical world.

At first, much of this new scientific inquiry focused nearly exclusively on the natural world. Great gains were made in physics, chemistry, biology, astronomy, and other fields dealing with the natural environment. It was not long, however, before the methods employed to achieve these gains were utilized in attempts to describe, explain, and predict human behavior. Hewing closely to positivism’s tenets, the social sciences sought to discover laws governing the social realm—in effect, laws that allow the predictability of human interaction. Subsequent years...
have shown just how elusive are the levels of predictability and precision found in the natural sciences when sought in the social sphere.

MORAL COMPONENTS
The need for a social science also emerged from widespread and often violent revolutions sweeping European intellectual, political, and economic spheres beginning in the seventeenth century. Economic crisis spurred on by widespread migration to urban centers, widening inequality, and the imperialist ambitions of some European states led many to apply scientific approaches to social behavior, in an attempt to understand and predict social phenomena. Implicit in this project was a distinctly moral component, which scholars such as Alan Wolfe argue is still central to the social sciences, even if it is not always evident in their practice (Wolfe 1989). While social science attempts an objective evaluation of human and social behavior, by its very nature it must grapple with questions of equality, fairness, cohesion, and happiness, and thus with moral issues.

SOCIAL SCIENCE’S METHODOLOGIES
As was the case with the natural sciences, much of the early social science literature relied heavily on human observation in deriving its conclusions. Not until the publication of Émile Durkheim’s Suicide in 1897 was statistical analysis incorporated into social scientific writings. With the subsequent increase in statistical analysis looking at all forms of social behavior, a divide was created within the social sciences between those using quantitative and those using qualitative methods. The proponents of quantitative methods often cite their predictive powers and the ability to develop generalizable properties via random samples—allowing social scientists the ability to sample the behavior, opinions, or values of a relatively small number of individuals and apply their findings fairly accurately to larger populations. Qualitative methodologists argue that their approach results in a more detailed and specific understanding of a given area of study. While at the start of the twenty-first century this divide still exists within the social sciences, a recognition of the need for a more integrative approach is beginning to emerge.

A third and somewhat distinct methodology emerged during the 1800s from the work of Wilhelm Wundt, generally considered to be the father of psychology. Wundt was one of the first intellectuals to utilize human experiments as a methodological tool for the social sciences—a method still predominant within psychology, but found to a lesser degree in the other social sciences.

ETHICAL CONSIDERATION
Throughout social science’s history, ethical as well as moral considerations have played an important and interesting role in shaping types of studies and areas of inquiry. It is this ethical and moral dimension that to a degree sets the social sciences apart from the natural sciences. With its main area of inquiry being the human animal, it has long been recognized that social science, if misused, poses a certain level of danger.

While they are rare, there have been social scientific studies that were physically or emotionally harmful to the individuals under study. Stanley Milgram’s electrical shock experiments in the early 1960s and Philip Zimbardo’s 1971 Stanford prison experiment are two of the more infamous cases of disregard for the ethical treatment of study subjects. Milgram, conducting authority experiments, led test subjects to believe they were applying dangerously high levels of electric shocks to other experiment volunteers. In reality, volunteers seemingly receiving shocks were accomplices who only acted as if they were being shocked. Despite being told of the deception after their participation in the experiment, some of the volunteers who were instructed to apply electrical shocks continued to suffer emotional stress caused by their initial belief that they had severely harmed or even killed another individual. Likewise, in 1971 Zimbardo, hoping to explore the nature of human evil, created a mock prison at Stanford University, subdividing volunteers into two groups—prisoners and guards. After only six days the experiment was shut down due to sadistic behavior on the part of the guards and the onset of depression in many of the prisoners. Much was learned from both of these classic social scientific investigations—which are still being studied several decades after they ended—but both also dramatically highlight the potential harm experiments can cause to subjects.

Another ethical issue confronted by social scientists concerns the use of scientific evidence to further dangerous or prejudiced ideologies, and the ways in which such ideologies can shape research results. In The Mismeasure of Man (1981), Stephen Jay Gould argues that racial and ethnic prejudices can influence social scientific research in such a way that the scientist’s ideological beliefs are reified by flawed research results. Gould shows how early craniometrical research attempting to link skull size to intelligence, and ultimately to a hierarchical ordering of races, produced severely flawed results that mirrored the preconceived prejudices of the scientists conducting the studies. The racist undertones of these and other early attempts at blending biology and the study of human behavior (to produce what was later coined sociobiology) have made many social scientists suspicious of biological explanations for social behavior. Nonetheless, by the second half of the
twentieth century achievements in evolutionary biology and genetics had sparked new interest in the link between genetics and social behavior.

Social scientists must also consider who will use their findings and the manner in which the findings will be used—especially when utilized by government and military institutions. While social science can provide much insight useful for the formulation of beneficial public policy, it also has the potential to be utilized in unethical ways. Such was the case in the United States after the September 11th attacks of 2001 which led to the War on Terror. The U.S. military turned to the social sciences, mainly psychology, to aid them in extracting information from combatants in custody. Questions were raised regarding the ethics of social scientists utilizing their expertise on human behavior to aid military and government interrogators extracting information from detainees in coercive ways, possibly amounting to torture. Ultimately, the American Psychological Association ruled its members could participate in the interrogations as consultants so long as noncoercive methods were utilized (American Psychological Association Task Force 2005, Behnke 2006).

SOCIAL SCIENCE’S BRANCHES
Differing perspectives on how social scientific inquiry should be applied and what it should be applied to led to the advent of several branches of social science, which, however, display greatly overlapping interests and methods and share a number of major thinkers in common.

Psychology Psychological, or the science of the mind, which is often traced to the work of Wilhelm Wundt in the mid-to late 1800s, attempts to explain the behavior of individuals through the mechanisms of the psyche. The related field of social psychology explores the mind’s operations in the context of interactions within a group. Increasingly, however, subfields within psychology have come to be seen as more akin to the natural than to the social sciences. With its increasing emphasis on biological development and on functions within the brain, psychology, perhaps more than other social sciences, is beginning to blur the line between the natural and social sciences.

Anthropology Anthropology is generally regarded as the scientific study of the origin, the behavior, and the physical, social, and cultural development of humans. According to Wolfe (1989) and others, anthropology’s general emphasis on origins has tended to make it only indirectly focus on contemporary society. While it is a broad field, most of its studies can be classified as belonging to one of four subfields: cultural anthropology, physical anthropology, linguistic anthropology, and archaeology.

Economics As with the other social sciences, there are multiple—if similar—definitions of economics. It is perhaps best defined as the study of the creation, consumption, and distribution of scarce resources. The field is broadly categorized into one of two subfields: macroeconomics and microeconomics. Macroeconomics emphasizes national-scale economies and their interactions, whereas microeconomics tends to focus on interactions between agencies, corporations, and individuals. While focusing primarily on markets, economics also explores how markets influence and shape other cultural phenomena.

Political Science Like social science’s other branches, political science is a diverse and broad field of inquiry. It is best understood as the study of power and its transfer through political behavior. Political science as a coherent and recognized branch of social science did not develop until the mid-1800s, although it is widely acknowledged that scholars and intellectuals before that time had been pursuing insights into political behavior for many centuries.

Sociology Sociology as a coherent and established field of study is the newest of the social sciences, and perhaps the most difficult to define. With its area of scientific inquiry being all things social, sociology is often seen by its practitioners as analogous to social science itself and as integrating the work done in anthropology, psychology, political science, and economics. Such a view is confirmed by the diversity of the thinkers sociology considers influential—many of whom came from other social-scientific disciplines. Karl Marx and Max Weber, recognized as two of sociology’s founders, were trained as an economist and a lawyer, respectively. George Herbert Mead, a philosopher, has had a lasting influence on sociology, as has Talcott Parsons, who had graduate training in economics. Likewise, anthropologist Margaret Mead, psychoanalyst Sigmund Freud, and many other non-sociologists continue to influence sociological research.

While at the start of the twenty-first century sociology, anthropology, political science, psychology, and economics are seen as separate and distinct branches within the social sciences, these disciplines continue to be linked together by a common grounding in the writings of a number of key thinkers. Among those that are still read by more than one social science branch are Adam Smith, John Locke, Sigmund Freud, Karl Marx, Émile Durkheim, and Erick Erickson, to name only a few.

CONTEMPORARY ATTACKS ON SOCIAL SCIENCE
During the 1960s, two then-emerging intellectual movements known as poststructuralism and postmodernism first articulated an attack on some branches of social science...
that continues to this day. As Pauline Marie Rosenau argues in *Postmodernism and the Social Sciences* (1992), from their birth both poststructuralism and postmodernism took very similar positions, and by the end of the twentieth century they were generally seen as synonymous with each other. Poststructuralism emerged from continental Europe in the 1960s in reaction to *structuralism*—the belief that basic structures governing human interaction can be found, despite its changing and often-times contradictory nature. Postmodernists shared the same reaction against structuralism but applied their critique to larger cultural entities. Because of their many commonalities, by the end of the twentieth century the term *postmodernism* was often used as an all-encompassing word to refer to both movements.

Postmodernism has many historical roots, but its direct origins can be traced to the work of poststructuralists such as Michel Foucault. By the late twentieth century, Jean Baudrillard had emerged as postmodernism’s leading theorist. Baudrillard as well as other postmodernists often draw inspiration from Friedrich Nietzsche’s nihilistic anti-Enlightenment philosophy, which questioned notions of truth. All claims to objective truth or knowledge, especially those produced through scientific inquiry, are seen by postmodernists as subjective “narratives” that need to be deconstructed and decentered, to reveal them as attempts at exercising and enforcing social power. Furthermore, the existence of ordered reality is denied, and the concept of “evidence” is attacked.

While postmodern thought can largely be attributed to French philosophers such as Baudrillard, Jacques Derrida, and Foucault, there are also American forerunners of postmodern discourse—namely C. Wright Mills, David Riesman, and Berger and Luckmann. Though not generally seen as postmodern thinkers, these Americans hinted at many aspects of postmodern thought prior to the emergence of the postmodern label.

**THE SOCIOLOGY OF SCIENCE**

Questions about the objectivity of social science have been raised not only by its critics, but from within the social sciences as well. Recognizing the inherently social nature of scientific inquiry, social science has been able to apply its methodology to the practice of science itself—and in so doing has called into question the claims of science, both natural and social, to be objective. Work by academics such as Thomas Kuhn, particularly his landmark publication *The Structures of Scientific Revolutions* (1962), as well as advances in the subfield of the sociology of knowledge, have called into question how objective scientific practices really are, and have begun to show that politics, personalities, and larger cultural trends often inform scientific endeavors. Science (and by default social science) is no longer seen as a steady accumulation of more and more data leading to incremental advances in knowledge. Instead, science and the knowledge it produces are seen as the product of social forces that often lead to revolutions within scientific fields, and dramatic paradigm shifts in what any particular science claims to be true at a given point in time. This realization during the mid-twentieth century marked a dramatic turning point in social science’s development. Social science, which previously had relied on the natural sciences as a model to emulate in its own development, could now apply its own knowledge and methods to the natural sciences—which were seen as areas of social behavior in need of study.

**SOCIAL SCIENCE IN THE UNITED STATES**

Social science achieved perhaps its purest form in America. For a number of reasons, metaphysical and epistemological concerns have largely been ignored within the United States, leaving such “philosophical speculation” to European counterparts—although British social science is more akin to that found in the United States. Academics such as Dorothy Ross in her 1991 work *The Origins of American Social Science* have argued that America’s particular brand of social science is the result of pre–Civil War American exceptionalism—the belief that America held an exceptional place in the world, outside of the historical currents that were leading to class uprisings and mass poverty elsewhere. By the mid-1800s, with the rapid industrialization of the United States, American social scientists were, however, finally forced to recognize the influence of historical forces on American society.

**SOCIAL SCIENCE IN THE TWENTY-FIRST CENTURY**

Social science’s direction at the start of the twenty-first century is difficult to discern. Increasing attacks from postmodernist thinkers provide some reason for concern. Perhaps more alarming, however, are the internal divisions confronting the social sciences. A wide array of sometimes competing methodologies and theories has led to frequent infighting among social science practitioners, and the absence of an accepted grand theory creates some level of worry about future directions. Some of social science’s branches, however, namely economics and psychology, seem to be gaining in prestige. In the case of economics, this is mainly due to the increasing weight given to the marketplace as a predictor of many facets of human behavior; in the case of psychology, it is due to the field’s growing ties to the biological sciences.

There are other positive developments afoot as well. Social science, especially within sociology and anthropology, has increasingly recognized the need for minority per-
spectives. As a result, an increasing number of minority scholars have made their way into the social sciences since the 1960s. New areas of study loosely affiliated with the traditional social science disciplines have also emerged: African American studies, Chicano studies, queer theory, and women’s studies, all of which have made important contributions to the social sciences. Furthermore, the social sciences have increasingly found a place in governmental and corporate entities, tackling everyday issues confronting society.

SOCIAL SCIENCE, VALUE FREE

The German sociologist Max Weber (1864–1920) is the originator of the demand for freedom from value judgments in the social sciences, an ideal he referred to as Werturteilsfreiheit (value-freedom). Weber argued that there is a logical gulf—it is not a matter of degree—separating the causal hypotheses and empirical generalizations of science from value judgments, that is, one’s moral, political, and aesthetic preferences. The “truth” of a social scientific hypothesis is in no way a matter of these preferences. No preference is, in turn, “required” by any given set of facts. Since this is so, it behooves social scientists to keep the two realms—fact and value, is and ought, science and values—separate.

In Weber’s day, this separation was not observed by everyone. “Professorial prophets,” as Weber called them, preached worldviews (Weltanschauungen) from university lecterns as if from the pulpit. It was for Weber a matter both of personal integrity and professional duty that this propagation of practical political ideals be brought to a stop (although he found it immensely hard to persuade his colleagues, who represented a range of “human” disciplines, to accept this view). These self-appointed “prophets,” Weber argued, indulged in a form of showing off. Worse, their pronouncements impaired the clear perception of reality (Weber’s own scientific vocation): Ultimate questions were addressed “in the name of science,” which is a logical impossibility. Such professorial “prophets” were paid from state funds (unlike religious preachers), were unsupervised, and did not anticipate any debate; the student audience in the lecture hall could not answer back, so academic power was abused. According to Weber, scholars and teachers should stick to their scientific vocation, for they have a job to do that requires addressing in a businesslike manner. In Weber’s philosophy, meaning cannot be given to the whole of existence, as the “prophets” seemed to believe. The teachers’ task is instead to present facts, even ones they may find personally unpalatable, and to always see these facts as separate from their own evaluations.

Weber was influential because he called attention to the vocation of the scholar in the human sciences—a job that demands a professional approach—at a time when such a view was rare. What, he asked, is the responsibility
of scholars to their discipline and to themselves, both as scholars and as political or moral beings?

**VALUE-RELEVANCE**

Weber held that values influence the way in which research is conducted in the social sciences (in addition to other non-essential ways common to natural and social science) and that values themselves could be affected by the results of research. The holder of a value position may learn that a course of action is unworkable or that, if pursued, other values might, collaterally, be infringed or impeded. Facts can be brought to bear on values, potentially affecting one’s holding of them. However, this does not weaken by one iota a given value’s freely-chosen status. On the research side of the human disciplines, evaluations enter into the subject matter. Using *verstehendes Erklären* (understanding explanation), that is, the subject’s evaluations seen in relation to the conditions of his or her action, the researcher can hope to sort out the decisive motives of the actor studied. In research, the scrutiny of values permits a discussion between investigators that can clarify the (evaluative) points of view each brings to bear.

Science is served, Weber believed, by an empirical, critical treatment of values. Ultimate values can come into view, and the implications of such values, when particular situations are judged in practical terms in their light, can be traced. In addition, the factual consequences of such judgments can be seen, and new ultimate values can be revealed (with their own implications) of which the maker of the judgment was not at the time aware. The choice of any given value is always, of necessity, “free,” that is, incapable of being determined by any fact. It is free because it is a value. It is a choice because there are many values and they are radically at odds, in Weber’s view (he called them “warring gods”), in the modern, a-religious world.

Both the investigator and the investigated are caught up in culture. “We are,” Weber says, “cultural beings” (1968, p. 180). If culture is to be their object, social scientists must recognize that the precondition for a cultural science is that, as cultural beings, humans can take up an attitude to the world and give it meaning and significance—some part of the world becomes culture for them. It is “values” that permit this. And, of course, concrete cultural values and hence “problems” in cultural science change with culture, shifting over time. “Value-relevance” (*Wertbeziehung*) was an idea Weber took from his friend Heinrich Rickert (1863–1936), a philosopher, although he modified it in the process. But his basic attitude to all of science is neo-Kantian in cast. Values are a component of human action and can be empirically investigated. Only their validity is unprovable empirically. It was Weber’s intense concern for reality that convinced him of the heterogeneity and historical nature of values, despite the teachings of the dogmatists who believed the world as a whole had but one meaning and of those philosophers who were striving to provide the means for finding such a meaning on the transcendental level. Weber believed that human beings must choose for themselves. Science must accordingly be kept value free. A concern for values underlay Weber’s commitment to freedom from value judgments in science (and teaching).

**THE VALUE-FREEDOM DEBATE**

Weber’s idea of value-freedom and value-relevance has been an object of continuous discussion since he formulated it. Critics have appeared in several guises. Analytical philosophers, for example, are concerned with the is/ought distinction; descriptivists maintain that all qualities of objects are assimilable to their factual properties; and some empirical sociologists argue that value-freedom is a conservative professional ideology. Given that society is dichotomously divided—between, for example, men and women, white and black, bourgeoisie and proletariat—and the dominant is biased, the sociologist must take sides; if the sociologist falls on the side of the weaker, he or she must be biased too. For critical theorists, Weber advocates “decisionism,” that is, he implies that value choice is blind faith and “private”; Weber is thus a (subtle) positivist. A public consensus on value matters (ideals and projects) is, however, possible via human action.

Similarly, but from the perspective of natural law theory, Leo Strauss (1899–1973) argued that Weber was ultimately a nihilist in moral matters, whereas a return to the tradition of classical political philosophy would make it possible to settle whether or not values are heterogeneous and in conflict, as Weber maintains. Weber provided a middle way between positivism and idealism that was itself a finely wrought solution to the key questions involved in the possibility of a “social” science. These questions continue to be asked, and Weber’s answers continue to be dissected by fresh generations faced with the conflict between reason and faith, science and values, theory and practice, and detachment and involvement. They share Weber’s insight that science “cannot save us” but believe, with him, that commitment alone is not enough.

SOCIAL STATICS

The concept of social statics relates to the assumption that the order of society is knowable. Without this basic premise, the study of the social sciences lacks rational predictability.

Social statics is the order of society. This order includes structural components (e.g., family, government, and economics) and the interaction between these components. Auguste Comte, the father of sociology, based social statics on the positivist philosophy. In creating the science of sociology, Comte moved the explanation of the hows and whys of society away from the theological and metaphysical toward the rational and scientific. This is similar to Plato’s basic assumption that the order of society is knowable and explainable, as illustrated in The Republic.

Comte identified the elements of “spontaneous order” of social statics as the individual, family, and society. Sociology does not focus on the study of the individual in the way that psychology does. For Comte, the simplest form of a social unit is the family. All other social units build upon the family unit. The reason Comte included the individual as one of the elements in social statics was to illustrate a primary function of the family as a social unit: to socialize the individual into a functioning member of society. The result of successful socialization is the expression of appropriate forms of interaction with all elements of society.

The interaction of the family social unit with the rest of society illustrates Comte’s concept of the division of labor. The division of labor is an operational definition of social statics. The interdependency of the division of labor holds together social structure and interaction in an orderly fashion. In the family structure there are roles that the husband, wife, and offspring play. For example, the role of the husband is interdependent upon the role of the wife. The family unit cannot fulfill its defined social purpose to reproduce and socialize offspring without the interdependency between husband and wife. Interactions focus on socialization of the members of the family unit for the benefit of the greater society as a form of social control. The division of labor creates not only interde-
Social Status

Social status has been used throughout history to differentiate individuals and groups of people in order to maintain hierarchical systems of inequality between and among people and to enforce the idea that certain groups of people are, by nature, born to a certain level of existence.

Social status is often described as one’s “standing” in society; the word status is derived from the Latin statum, meaning “stand.” In a narrow sense, the term refers to one’s legal or professional standing within a group; in a broader sense, it means one’s value and importance in the eyes of the world (de Botton 2004, p. vii). At various points in history, the belief that inequality was a way of life was subscribed to by both the oppressed and their oppressors in terms of religion, law, and cultural norms. History, law, and cultural artifacts show that in nearly every society, certain groups of people were held in high esteem while others were ignored or ridiculed. Historical events such as the French Revolution, the American Revolution, and the civil rights movement largely transformed societies, moving them away from hierarchical ladders that restricted upward mobility because of heredity, lineage, family, gender, race/ethnicity, skills, physical attributes, religion, accent, and temperament.

The desire for social status can spur individuals to act on their dreams, achieve goals, and form a common bridge with others. Often, though, individual achievement has not been considered a factor when comparing one’s social standing in a community. According to Alain de Botton in Status Anxiety (2004), “what mattered was one’s identity at birth, rather than anything one might achieve in one’s lifetime through the exercise of one’s faculties. What mattered was who one was, seldom what one did” (p. 87).

HISTORICAL PREVALENCE

According to de Botton, the characteristics of groups that historically have been considered high status can be traced from Sparta in 400 BCE to Brazil in 1960. Such characteristics have ranged from military training, wealth, power, sainthood, knighthood, social graces, and hunting ability to those with the ability—physical, intellectual, and artistic—to persuade and/or bully other groups into offering respect or a redistribution of favor. Derrick Bell, in Silent Covenants: Brown v. Board of Education (2004), relates social status to race/ethnicity, access to opportunity, and the reflection of persons of color when discussing issues of privilege and status. According to Bell (2004), “Du Bois reminds us that to compensate their low wages, segregation gave whites a ‘public and psychological wage’…. David Roediger adds that status and privileges could be used to make up for alienating and exploitative class relationships, North and South” (p. 81).

THEORETICAL DEVELOPMENT AND RESEARCH

Theories have been developed to describe social status, class, and identity. Similarly, social status has been described in terms of international dominance and competitiveness between countries. The desire for social status to plunder other nations in the quest for international superiority. Said frames social status in terms of a country’s plunder and conquest under the aegis of “a civilizing mission, the idea that some races and cultures have a higher aim in life than others; this gives the more powerful, more developed, more civilized the right to colonize others in the name of a noble ideal” (p. 333). The historical underpinnings of social status can be traced to the Greeks. Said states that “each culture defines its enemies, what stands beyond it and threatens it. For the Greeks beginning with Herodotus, anyone who did not speak Greek was automatically a barbarian, an Other to be despised and fought against” (p. 355).

Social status is often viewed through the lens of comparing groups along specific criteria and the relationship between groups. According to Suls and Wheeler (2000), Newcomb’s 1943 analysis of college student political atti-
attitudes revealed that “people use groups or social aggregates as standards or frames of reference when evaluating their abilities, attitudes, or beliefs” (p. 85). Similarly Suls and Wheeler state that “Roper (1940) first introduced the idea of a reference group by suggesting that individuals’ perceptions of their own status depends on where they stand in relationship to other people” (p. 85). Abowitz (2005) conducted a recent study of undergraduate college students to ascertain their views of the American class system. Based on a survey of a random sample of 154 undergraduate students, Abowitz reported that college students believe that they can achieve a certain social status through individual factors that are part of, as the author states, an achievement ideology, “the idea that success and social standing are largely a product of individual effort and not a product of family privilege and connections” (p. 716).

SOCIAL STATUS MEASUREMENT
According to classical research conducted to understand the role of student persistence in college, background characteristics of students and their social status were some of the most reliable predictors of success. Similarly, Tourtoushian and Curtis (2005) found that the socioeconomic status of specific school districts can help explain variations in students’ average standardized test scores, college attendance, and school rankings. Sociometry, a systematic method for investigating relationships, was used in Kosir and Pecjak’s (2005) study to determine whether students were categorized by their peers as having social status and popularity. Based on the results of their research, Kosir and Pecjak found that peer-perceived popularity is a construct that is distinct from sociometric popularity.

Other studies of social status involve the predictive value of subjective assessments of social status with an individual’s health status. Research by Operario, Adler, and Williams (2004) based on a national sample of 500 adults, ages eighteen and over, used the Scale of Subjective Status. Participants were instructed to do the following:

Think of a ladder with 10 steps representing where people stand in the United States. At step 10 are people who are the best off—those who have the most money, the most education, and the most respected jobs. At step 1 are the people who are worst off—those who have the least money, least education, and the least respected jobs or no job. Where would you place yourself on this ladder? (p. 241)

For this portion of the research, “the sample rated themselves on average above the midpoint of the scale at both baseline and follow-up” (Operario et. al. 2004, p. 241). Including measures of global health and health risk factors, the authors found predictive utility in self-report measures of socioeconomic status and individual health status.

Levin (2004) measured social dominance by groups that want to have a higher status than other groups using such distinctions as religion, ethnicity, and gender. Using a social status questionnaire, Levin found that differences in social dominance between arbitrary groups (e.g., ethnicity and religion) was greater when the status gap between the groups was perceived to be larger.

Thus, social status, depending on the historical time frame, country, and culture, can be delineated through one’s resources and achievement. However, the hierarchy suggested by comparing one’s standing with others still exists and is prevalent in societies where resources and power define the influence that one or a group has. This power and influence permeate aspects of governance and the place each person subscribes to with reference to an individual’s or a group’s relative value and standing.

Social Structure

Social structure refers to durable features of sustained, large-scale, social coexistence that shape individual conduct. Attempts to summarize the nature of human society are often said to offer accounts of social structure. Such accounts vary but typically include claims addressing five facets: (1) collective features, process, or patterns that are consistent across large populations and (3) persist for long periods and that are manifest as impersonal and implacable influences that strongly condition (5) the lives that individuals can lead. Claims to priority for particular accounts are sometimes advanced as “structuralism”—assertions of precedence for particular impersonal, extra-individual, or collective features. In polemic usage, the label has accompanied wide and varied claims of displacing superficial or shallow alternatives in favor of deep, overarching generalizations about human conduct, language, or cognitive capacities.

All social sciences incorporate some variants of the concept, but the issues posed by social structure roughly coincide with the disciplinary charter of sociology. Seminal contributions (and their authors) are often lauded for providing distinctive visions of social structure. Since such efforts address the ultimate nature of human society, they are best understood as charter statements that unite followers (and antagonists) into schools whose agreements (and disagreements) extend to the nature, content, and value of the master texts.

Karl Marx (1818–1883) traced the origin of social structure back to the necessity for humans to wrest sustenance from nature through labor. However, the results of labor include matters that have been gathered and reshaped and that if put aside today will add to the fruitfulness of any further labor. Thus fields cleared of forest, iron forged into plows, or grain not eaten but kept for seed become means of production—products of past labor that can be added to future labor to make it more fruitful.

Any society thus must address the problem of who will be assigned control of the means of production. Marx observed that the products of work, built up over generations, became the property of a relative few, who could then assign to themselves the lion's share of the product of future work, without themselves having to do it. He suggested that collective life, including religion and politics, would be constrained to perpetuate such a division of the population into unequal classes. Individual outlooks and actions would tend to conform to interests arising from class positions. And the classes would be linked into antagonism until the growing scale of factories would insure the ascendance of the propertyless in a revolution abolishing property and bringing on a new social structure of a classless society.

Emile Durkheim (1858–1917) underscored that matter was not property unless nonowners respected owners’ claims. Markets required moral solidarity to ensure that contracts were honored, for example, constraining buyers and sellers from grabbing away goods or payments without relinquishing what they had offered in return. More broadly, Durkheim argued that absent moral limitation supplied by society, humanity's inherently insatiable desires would lure humans into vice and unreliability as workers, family members, or citizens.

Durkheim argued that moral sentiments shared in common formed social facts—enduring, extensive, external forces that constrained individuals into moral conformity. He offered three complementary accounts of how this might work.

First, Durkheim suggested that the force of society would wax and wane with the overall volume of interaction in a population, suggesting that the impact on individuals rises and falls as moral messages are repeated to them more or less frequently. In turn, the average frequency (and consistency) of moral messages arriving at each individual reflects the totals received and retransmitted by the individual's interaction partners, taken en masse. In this manner, the moral sentiment impinging on individuals arises from collective, accumulated experience that is external and beyond individual control. Second, Durkheim also suggested that participation in collective celebrations, notably religious worship, would amplify and reinforce moral sentiments expressed through such ceremonies. Third, Durkheim feared that inconsistent messages, generated by participation in diverse groups that upheld contrasting normative outlooks or participation in groups unwilling to specify clear moral standards, would result in a state of normative dissonance or weakened moral regulation that he termed anomie.

Max Weber (1864–1920) also took issue with Marx's insistence on the primacy of economic factors. He called attention to contrasts rooted in religious outlooks and in other sources of diverging worldviews. Weber thought the common element uniting social structures was learned adherence to schemes of values—abstract ideals spelling out goals and pitfalls. These might include how to serve God (after specifying what God or gods to serve), or the unlimited pursuit of gain, or putting obligations to kin ahead of obligations to the ruler.

Values are highly abstract and often are only expressed indirectly through parables, stories, sermons,
and the writings of sages. From these, readers, commentators, and legislators work at deriving further rules that people should follow. For Weber, uniform or structural regularity across a population was the result of enmeshing in a web of norms—morally binding rules that reflected values held in common. While Weber recognized that values and their derivative norms could derive from tradition, or from religious inspiration he termed *charisma*, he also emphasized that rules were subject to extension and elaboration through reasoning by experts who were learned in the code. He feared that such expanding rationality would come to confine humanity in an "iron cage" of intricate but colorless regulation.

Specialists continue to seek to purify and refine seminal visions. Most sociologists accept that many categorical contrasts, such as race, class, and gender, are collective durable features of large populations that shape lives. Many would extend this list to include the principle categories used to sort and count people in censuses and surveys—the demographic variables including age, ethnicity or national origin, religion, education, and so forth. All of these variables strongly condition a wide range of behaviors including friendship, marriage, political preferences, consumer choices, and much more.

Why and how this occurs remains open. Some would insist that such regularities require that individuals act as if extant rules and social definitions are binding. The puzzle is what (if anything) is adequate to account for assent to unequal outcomes on the scale that is required.

An alternative is that durable features reflect how (and in what degree) categories channeled persons into different settings, social pairings, and uses of time. A principal motive is that power-holders can address recurrent organizational dilemmas by drawing on widely understood social classifications to allocate work, authority, or rewards. Any population consists of individual histories that incorporate the (variable) past degree of such sorting, along with assorted consequences and correlates. Classifications are guides (of varying accuracy) to similarities and contrasts in past experience that, in turn, influence individuals and power-holders in subsequent choices over settings, pairings, and time use.

**SOCIAL SYSTEM**

The concept of social systems became central to sociology with *The Social System* of Talcott Parsons, published in 1951. Parsons’s formulations were modeled on concepts of homeostasis developed in physiology rather than simpler notions of equilibrium used by Vilfredo Pareto and other earlier theorists. Parsons portrayed equilibria in social systems not as static balances among forces but as complex interdependencies involving mutual adjustments among many independent components. He emphasized that social systems are moving equilibria that accommodate change while maintaining overall stability. He noted that equilibria can break down, resulting in anomic, strain, and conflict.

**SCOPE OF THE CONCEPT**

For the system concept to be useful in sociology, Parsons held, it required adaptation to the empirical nature of social reality. Social systems are not concrete, directly observable entities but rather analytically defined domains of objects. They can be identified only by abstracting social interaction, relationships, and institutions from enveloping phenomena—physical-chemical, biological, psychological, and cultural. Yet, social systems also interpenetrate, or share elements with, their environments. They exist in time, space, and ecological settings. They gain structure by institutionalizing values and norms that have their sources in cultural systems. Their members’ affective attachments to normative orders and motivation to pursue socially validated goals derive from personality systems.

Social systems vary in size and duration. Brief interactions between individuals can be treated as social systems. So can large-scale societies that endure for centuries, such as Chinese civilization. Institutions of intermediate scale—the business corporation, medical practice, or electoral politics—are social systems. Complexes of institutions, such as modern metropolises or global trade, may be analyzed as social systems. Individuals participate in many social systems, typically adopting different social roles in each—employees in business firms, members of political parties, fathers or mothers in families.

Parsons viewed social interaction as a dynamic give-and-take of expectations among independent actors. Actors support their expectations with sanctions, invoked
contingently on others as rewards when expectations are met or as punishments when expectations are broken. Parsons held that an actor’s behavior, even in simple relationships, is doubly contingent, dependent on expectations and sanctions held by both the actor and other parties. Because of different experience and exposure to social strains, actors often hold conflicting expectations for performance of their own or others’ roles. Conflicts in expectations emerge in everyday interaction, as between parents and children, and in role relations of macrosocial importance, as between a president and members of Congress over legislative oversight.

Conflicts over role expectations may release powerfully motivated pressures to change roles and the institutions that coordinate them. After adjustment in roles and underlying norms and values, new equilibria may emerge. Motivation that is deviant from previous role expectations may thus be a source of creative social change. Yet, role incumbents mobilize sanctions to counter deviant expectations and are generally able to suppress potential change. Social institutions tend to reimpose established equilibria, whether through informal interaction, the procedures of formal organizations, or legal procedures.

THE FOUR-FUNCTION PARADIGM

Parsons identified four general system problems that all social systems confront. He called them functions and treated them as general dimensions of the organization of social systems. The idea of a closed and ordered set of functions applicable to all social systems was a radical innovation. Previous functional theories had been based on open-ended lists of functions without limitation in theoretical principle. The four-function paradigm provided the conceptual frame for Parsons’s work after the mid-1950s.

The four functions are:

1. Adaptation, or the gaining of control over conditions in environments of the system. Adaptive processes involve developing new resources or improving allocations of resources to strengthen a system’s capabilities and efficiencies.

2. Goal attainment, or the processes of organizing the activities of social units to bring about a valued state in the system’s relationships to its environments, typically including other social systems.

3. Integration, or the processes of mutual adjustment among a system’s components to promote their long-term dependence on one another and attachment to the system.

4. Pattern maintenance, or the processes of developing long-term commitment to values and other principles that distinguish the system from its environments.

Parsons proposed that the four-function paradigm might outline the primary dimensions of structural differentiation in societies. He thus developed a theory of four functionally specialized subsystems of society, with each subsystem treated as a complex set of interdependent institutions, even subsystems of their own. The four subsystems of society are:

1. The economy serves the adaptive function. In modern societies, it includes the markets for labor and capital, the business corporation, entrepreneurial roles, and the legal institutions of property, contract, credit, and employment.

2. The polity serves the goal-attainment function. In modern societies, it includes government agencies, including administrative, executive, legislative, and judicial authorities.

3. The societal community serves the integrative function. It encompasses ties of social solidarity, including social classes, status groups, voluntary associations, lifestyle groups, ethnic groups, and extended kinship groups. Phenomena of integration, stratification, and conflict are shaped largely by institutions of class structure, status order, and primordial ties, but also by common law, informal normative orders, and public opinion.

4. The fiduciary system serves the pattern-maintenance function, centering on development of the shared values and culture of a society. Its major institutions concern religion, family, socialization, and education. Following Max Weber’s emphasis on religious ethics, Parsons argued that change in fiduciary systems has been the greatest source of long-term macrosocial change.

Parsons’s theory of societal subsystems was never fully detailed, despite two decades of efforts to analyze the institutional structures of the four systems. He argued that each subsystem has its own forms of inequality, and the chief institutions of the respective subsystems—economic exchange, relationships of political authority, solitary ties in status groups, and socialization in family life—are intertwined with factors such as race and ethnicity, gender, cultural background, and educational differences, although in historically variable ways. He also argued that institutions in each subsystem integrate normative and interest-driven elements and ideal and material factors. Where social control is effective, the pursuit of self-interest reinforces the controlling normative institutions, as when the conduct of business relies on institutions of property, contract, and employment.
THE GENERALIZED MEDIA

Functional theory holds that the differentiated subsystems of society are mutually dependent. Each subsystem can fulfill its specialized function only if the other subsystems fulfill their functions. Applying this proposition to social processes as well as structures, Parsons hypothesized that each subsystem needs resources from the other subsystems to carry out its own processes. He developed a model in which the four subsystems are linked through six double interchanges, or exchanges of resources, between pairs of subsystems. A basis of this model was the economists’ treatment of circular flow between business firms and households (wages for labor, consumer spending for goods and services), which Parsons identified as the interchange between the economy and the fiduciary system. He then outlined five other double interchanges.

Noting that money is an essential mediator of economic processes, including circular flow, Parsons identified additional symbolic media that regulate processes for the other three societal subsystems. He proposed that power is the symbolic medium of the polity, influence is that of the societal community, and commitments are that of the fiduciary system. Identifying the set of symbolic media that regulate processes within and across the boundaries of the four subsystems greatly advanced theoretical analysis of equilibrium processes in society.

LUHMANN AND AUTOPOETIC SYSTEMS

In the years after Parsons’s theory of social systems reached maturity with the concepts just discussed, the most original thinking about social systems came from German sociologist Niklas Luhmann. Luhmann was influenced by Parsons and retained some of his terminology but developed a distinct theory.

Luhmann’s conception of social systems emphasizes not equilibrium but autopoiesis, a term he adopted from biological theory. Autopoetic (literally, self-producing) systems are capable of self-reproduction of their components. Luhmann emphasized the self-organizing, self-sustaining qualities of social systems and their components, not balances among components, as in equilibrium theories. Luhmann adhered to functional analysis but treated function as a relationship between a system and its multiple environments. Presenting his conception as continuous with Darwinian natural selection, he suggested that autopoetic systems are adaptive within specific ecological settings.

Luhmann emphasized that autopoetic systems of all kinds emerge by reducing the complexities of organization among the various systems in their environments. Every system represents a reduction of antecedent environmental complexities. Biological systems reduce the complexities of their physical and chemical environments. Psychic and social systems emerged as reductions of biological as well as physical-chemical environments. Once social systems evolved, they maintained intricate dynamic relationships with their environments—psychic, biological, and physical-chemical. The relationships with psychic systems are especially important as they, too, are systems of meaning, and meanings pass back and forth between psychic and social systems. Social systems themselves evolve to complexity as a natural process of adapting to their varied and intricately organized environments. Their complexity then creates opportunities for the emergence of new systems within themselves—subsystems—by the same principle of reduction of complexity.

COMMUNICATION AND SOCIAL SYSTEMS

Luhmann, defining social systems as systems of communication, used information theory and cybernetics to analyze processes of communication. He criticized transfer theories of communication, emphasizing that one does not give up anything when communicating ideas to another. Moreover, what the other receives is not necessarily the message originally intended. He accordingly focused the analysis of communication on how it changes the recipient. Communication in this view selects among open possibilities, confirming some possibilities while ruling out others. After receiving a communication, a person knows to orient future conduct to certain possibilities and leave others aside. Communication often occurs simply in physical gestures, but its meaning may be shaped, conveyed, or amplified through three classes of media: language, as used in everyday exchanges between individuals; the media of dissemination in written, print, or electronic forms, which can reach large or specialized audiences over extended times and places; and the symbolically generalized media that act on the relation between motivation and the selective effects of communication. The symbolic media help to connect communication with macrosocial structures, but Luhmann did not match the media to specific subsystems of society, as did Parsons. He gave different lists of symbolic media in his works, but generally included truth, love, money, power or law, and religious or ideological belief.

The symbolic media also serve, Luhmann suggested, as catalysts for the differentiation of society. He rejected Parsons’s four-function theory of societal subsystems, maintaining that subsystems emerge only by exploiting particular opportunities to reduce complexity in environments. Thus, the emergence of subsystems in particular societies can be identified only through analysis of the historical conditions that created the opportunities for reduction of complexity. Nevertheless, Luhmann identi-
fied law, politics, economy, religion and ideology, and science as common subsystems of modern societies. Each of the subsystems contains historically evolved semantic codes for regulating communication, codes that also regulate uses of the symbolic media. Issues of discrimination by race, ethnicity, gender, or cultural background can be understood by analyzing the semantic codes of specific media.

CONCLUSION
Parsons’s conceptual scheme was designed to guide empirical research in sociology and related social sciences. Over a period of several decades, a substantial body of empirical studies has been conducted in its terms, with many of the studies standing as major contributions. Luhmann developed his theory of social systems with greater concern for meta-theoretical issues than empirical research. Its long-term influence will likely derive from the critical perspective it provides on other theories. Both bodies of theory demonstrate the importance of theoretical analysis of social systems, yet both also leave significant issues open to further investigation.

SOCIAL THEORY
Social theory begins with ordinary questions, like why do some passively accept authority while others respond with political violence? Religions provided answers in a distant past. Social theory emerged as a secular alternative, often joining ethical and positive elements. Three traditions of social theory are important for the social sciences.

A first tradition comes from Thomas Hobbes (1588–1679). After years of bloody warfare between Catholics and Protestants, Hobbes’s Leviathan (1651) offered a worldly theory of social order. What was really at issue was power. As an early example of what would be termed ideology critique, Hobbes asks “cui bono?”—whose interest does this idea serve? People obey, he argued, because of fear of violent death. Social order thus turns on who has ultimate power over violence. If there is not one final authority, there would be war of all against all, and life would be “solitary, poor, nasty, brutish, and short.” Better, he argued, is a society founded on fear of a great leviathan, whose power guarantees stability.

Leviathan relied on no Absolute Good, whether God or Nature. In tracing all “higher” ideas to “lower” things—power, fear, death, the body, violence—Hobbes set the tone for one main strand of social theorizing. This approach continued in writers from Karl Marx (1818–1883) to Michel Foucault (1926–1984) and Pierre Bourdieu (1930–2002). While each differs, they are Hobbesian in asking “cui bono?”—and answering with a complex power struggle, even if it is denied, for example, in art, religion, and morality. This first type of social theory ferrets out hidden power structures behind everyday interactions and institutions.

Hobbes’s stress on fear led others to ask: Does not social order depend on more? What of obligation or love? How could the passions of a millennium and a half of Christianity be redirected onto earth, without producing the disastrous consequences Hobbes feared?

Such questions led to a second strand of social theory, stemming from Jean-Jacques Rousseau (1712–1778). He emphasized not fear but devotion as the foundation of social order. In our long-forgotten natural condition, Rousseau argued, we were independent, loving ourselves for ourselves; but society creates new needs, amour propre. We love ourselves based upon how much others love us. Not power, but the struggle for recognition and status regulates social order.

For Rousseau, justice can transcend nature and inequality. Justice depends in turn on the social contract, wherein each person must totally submit to the general will. Private freedom, he argued, depended on public equality, which required a “lawgiver.” Moreover, the social bond, to last, should be held sacred.
Karl Marx (1818–1883) and V. I. Lenin (1870–1924) transformed the lawgiver into the revolutionary vanguard; the redefined social contract was the abolition of private property, as the condition of freedom and justice. Émile Durkheim (1858–1917) later pursued Rousseau’s connections between social solidarity and religious sentiment.

Critical theorists—Theodore Adorno (1903–1969), Max Horkheimer (1895–1973), Herbert Marcuse (1898–1979), Axel Honneth—explored how modern societies create vast inequalities, not only in wealth, but respect and self-worth. They expanded Rousseau’s ideas that culture can create unnecessary dependencies, focusing on the “culture industry”—the popular press, music, movies, advertising, and fashions. These sought to promote “needs” like Marx’s false consciousness, where people became blinded to their own interests and dependent upon corporate and political masters. Some, like David Riesman (1909–2002), extended Rousseau’s *amour propre* to the 1950s conformism of American “other-directedness,” while others, like Daniel Bell, analyzed how politicians and corporations could shift the erotic into a political ideology. Thus social theory identified key foundations of power, even if exercised in subtle arenas.

These first two traditions invoke a strong state to right social wrongs, as theoretically defined. The third tradition is more cautious. Alexis de Tocqueville (1805–1859) was equally concerned with the roots of order and governance, but took a different course. Writing after the French Revolution (1789–1799), Tocqueville the aristocrat pondered the implications of equality. Societies emphasizing equality—like postrevolutionary America and France—were hostile toward exceptional talent and excellence; they could level out uniqueness and difference, generating a middling mediocrity. Moreover, equality threatened social identity and meaning: In a hierarchical society, one knew one’s place and did not have to anxiously make one’s place. In equalized societies, all is in doubt: Foreign observers regularly noted that Americans suffered a permanent “identity crisis,” which was spreading globally at the beginning of the twenty-first century.

Traveling across America, Tocqueville commented on the deleterious effects of equality, and potential remedies. Loosed from primordial hierarchies, Americans, he argued, developed a passion for voluntary associations. The town hall and the local church were key examples, sustained by their members’ voluntary efforts more than the weight of tradition or the power of elites (or a leviathan or lawgiver). What mattered was commitment by each participant, and Americans were joiners. The strongest social structures, Tocqueville argued, emerged not just through struggles for power or regard of others, but by citizens voluntarily developing shared commitments in local associations, which trained future leaders.

Tocqueville’s voluntaristic, bottom-up approach informs a third strand of social theorizing. Max Weber (1864–1920) stressed voluntarism in probing the religious roots of capitalism. Capitalists did not just strive to make money. Rather, Weber argued, Puritan sects encouraged their members to seek salvation in voluntary, committed “good works”—against the old nobility that valued leisure over work. Capitalism was the unintended consequence. Though Weber felt we inherited an “iron cage” of capitalist society that we did not choose, his response was voluntaristic: If you are a scholar, do it as a “vocation,” not as a heartless specialist; if you are a politician, lead, do not act as a technocratic bureaucrat. Voluntary commitment was key. In egalitarian America, every social interaction among equal citizens became a source of identity, obligation, and meaning, following G. H. Mead (1863–1931), C. H. Cooley (1864–1929), and Herbert Blumer (1900–1987). Talcott Parsons (1902–1979) extended voluntarism to critique past social theories, but like Weber joined basic values with individual choices. Edward Shils (1911–1995) and Daniel Elazar (1934–1999) continued Tocqueville’s concern for hierarchy, honor, and glory, noting that even within an egalitarian society, they remain social powers. Still others, such as Robert Putnam, suggest that the individualistic strain in voluntarism has gone so far in contemporary American life that the commonwealth Tocqueville saw had weakened, as more Americans “bowl alone.” Some postmodernists are so individualistic and egalitarian that they deny the possibility of meaning beyond the minds of separate individuals.

These three traditions have been revised and combined in efforts to interpret deep social changes. Consider the rise of industry, the division of labor, and bureaucratic organization in the theories of Marx, Durkheim, and Weber.

Marx, working in London, wrote of the English countryside transformed by industrial manufacturing; he saw people from all races and religions living near factories. These proletarians were a nascent class, opposed to capitalist/owners of the forces of production. In his theory, conflicts between such classes drove history.

Durkheim saw similar changes, but focused on the division of labor. Traditional societies, he argued, held together from pressures toward homogeneity. Modern societies are more like organisms. Social cohesion arises from interdependence; individuals perform specialized functions and develop a heightened sense of uniqueness. But without some firm social regulation, normlessness or “anomie” can undermine differentiated societies. Talcott Parsons and Niklas Luhmann (1927–1998) extended Durkheim’s social differentiation into multiple, interconnected subsystems that fill different social functions, while
others, such as Robert Merton (1910–2003), developed the idea of anomie and deviance as central to modern life.

Max Weber, writing in Germany, stressed the hierarchical rationality of government bureaucratic officials. Bureaucracies are ancient, but Weber stressed how modern organizations grew ever larger, more rational, and more hierarchical. Not only was the bureaucrat's personality stunted by his duties, everyone risked bureaucratization—since it was balanced increasingly less by the charisma of religion or respect for tradition. Seeking a "value-neutral" perspective, Weber posited that modern society is increasingly subject to "rational authority," as opposed to "traditional" or "charismatic authority." But the theory also had a quasi-moral intent, namely, to provide modern models for styles of action—rooted in the bonds of tradition or the electricity of charisma—which Weber saw threatened by the cold, abstract rationalism of bureaucracy.

Rationality was a political weapon that Enlightenment philosophers used to attack the "irrationality" of the ancient regime before the French Revolution of 1789. The secular theories of Hobbes and Rousseau helped refocus thinking on specific secular arrangements, rather than divinities or kings. But the legacy of this rational approach proved so powerful that Weber feared its excess. Analysis and criticism of rationalism in modern society have been among the most doggedly pursued strands of twentieth-century social thought, especially by Jürgen Habermas and other critical theorists and postmodernists.

Since Marx, Durkheim, and Weber, social theories have continued to stretch the imagination, seeking to capture the times and perhaps guide them. New topics emerge with new social forces: the massive rise of cities and new urban lifestyles; mass media, electronic media, and mass education; increased global interconnection; general increase in leisure time across societies; and a resurgence in the global power of religions are but a few of the subjects whose causes and meanings social theorists continue to pursue.

**SOCIAL WELFARE FUNCTIONS**

Social welfare functions have occupied the center stage of welfare economics since the philosopher Jeremy Bentham (1748–1832) and other utilitarian theorists advocated that humans should seek the greatest total welfare, understood as the sum of individual utilities. The noted economists Abram Bergson (1914–2003) and Paul A. Samuelson (b. 1915) generalized the concept. Following the seminal work of the economic theorists Kenneth J. Arrow (b. 1921) and Amartya K. Sen (b. 1933), the theory of social choice has examined the various possible forms of such functions in detail.

In the most standard form, a social welfare function is a mapping that determines the level of social welfare as a function of individual levels of welfare. In fact, a numerical measure of social welfare is not really needed for the evaluation of social situations; the only relevant part of a social welfare function is how it ranks social situations from the best to the worst.

The theory of social choice analyzes two important features of a social welfare function. The first feature is its degree of aversion to inequalities between individual levels of welfare. For instance, the utilitarian function, computed as the sum of individual indices of welfare, is indifferent to inequalities because only the total matters. In contrast, the maximin function, which identifies social welfare with the welfare of the worst-off individuals in the population, displays an infinite aversion to inequalities since it gives absolute priority to the worst off. There are countless intermediate possibilities between these two extreme functions. The second important feature of a social welfare function is the information about individual indices that is used by the function. For instance, the utilitarian function focuses on individual gains and losses when it compares two situations: A situation is better than another if the sum of welfare gains when one moves to it is greater than the sum of
losses. By contrast, the maximin function focuses on individual levels: A situation is better if the level of welfare of the worst-off individuals is greater. The link between the two features—inequality aversion and informational basis—has been thoroughly scrutinized by the theory of social choice. For surveys, see Walter Bossert and John A. Weymark’s “Utility in Social Choice” in the Handbook of Utility Theory (Barberà, Hammond, and Seidl 2004, pp. 1099–1178) and Claude D’Aspremont and Louis Grevers’ “Social Welfare Functionals and Interpersonal Comparability” in the first volume of the Handbook of Social Choice and Welfare (Arrow, Sen, and Suzumura 2002, pp. 459–542).

The link between the measurement of social welfare and the measurement of inequalities has also been clarified. The level of social welfare in a given situation can be decomposed into the positive contribution of total welfare and the negative contribution of inequalities. More precisely, it is generally possible to write social welfare as the difference of two terms. One is the sum of individual indices of welfare. The other, which comes as a deduction, is computed as the product of an inequality index and the sum of individual indices. In other words, one can typically say that inequalities reduce social welfare by a certain percentage, and this percentage itself is the value of an inequality index. Classical analyses of this link are provided by Anthony B. Atkinson in his essay “On the Measurement of Inequality” (1970) and Amartya K. Sen and James Foster in their book On Economic Inequality (1997).

A controversial issue has been the possibility of constructing social welfare functions on the sole basis of individual ordinal and noncomparable preferences over the social situations. The standard social welfare function relies on individual indices of welfare, but in its most general form it can simply define a ranking of social situations as a function of the preference rankings of these situations for each member of the population. This is important because there is much skepticism in economics about the possibility of making interpersonal comparisons of welfare in a consensual way. Bergson and Samuelson argued that the construction of a purely ordinal social welfare function was possible, but Arrow, in Social Choice and Individual Values (1951), provided an impossibility theorem and identified a deep problem in the idea of “aggregating” individual ordinal preferences. This problem has been questioned, however, because Arrow’s theorem involved restrictive conditions that do not appear compelling and are not even considered in important branches of welfare economics, such as the theory of fair allocation or cost-benefit analysis. It is now emerging that interesting social welfare functions can be based on individual ordinal and noncomparable preferences, in particular on the basis of the equity concepts developed by the theory of fair allocation. Overviews of the controversies can be found in Marc Fleurbaey and Peter Hammond’s contribution, “Interpersonally Comparable Utility,” to the Handbook of Utility Theory (Barberà, Hammond, and Seidl 2004, pp. 1179–1285) and in an article by Marc Fleurbaey and Philippe Mongin (2005).

RECENT DEVELOPMENTS

Recent developments have dealt with the refinements of social welfare functions to incorporate a variety of fairness concepts or to make it possible not only to compare social situations for a given population, but also to compare social situations across different populations. The latter is important to make judgments about the desirable size of the population, and deep dilemmas plague this issue. A social welfare function such that every addition of an individual with positive welfare is considered to improve the social situation will generate extreme populationist evaluations—for example, the judgment that a larger population always makes a situation better, provided the larger population is large enough, no matter how low individual welfare is in this situation. However, a social welfare function that is based on some notion of average individual welfare is likely to be Malthusian because any addition of an individual with less-than-average welfare is considered undesirable. The compromise proposed in Population Issues in Social-Choice Theory, Welfare Economics, and Ethics (Blackorby, Bossert, and Donaldson 2005) is to define a critical level such that the addition of an individual is good only if his welfare is above this threshold.

An important issue in fairness concepts has been the incorporation of considerations of freedom and individual responsibility, motivated by theories of justice such as that of John Rawls (1971). Social welfare functions have been developed that are based on the idea of measuring individual situations in terms of opportunities or resources rather than ultimate welfare. A variety of functions have been proposed, in particular because there are different possible interpretations of the implications of individual responsibility. In one interpretation, individual responsibility removes the need for redistribution, which has motivated the construction of social welfare functions that disregard individual characteristics for which the individuals are responsible and focus on the compensation of inequalities for which individuals are not responsible. In another interpretation, individual responsibility removes the need for inequality aversion in the evaluation. Along this vein, social welfare functions have been proposed that are of the utilitarian sort along the responsibility dimensions of individual characteristics and of the maximin sort along the non-responsibility dimensions. Surveys of this field can be found in John E. Roemer’s book Theories of Distributive Justice (1996).

**SOCIAL WELFARE SYSTEM**

The social welfare system refers to “the whole set of modern social programs offering income maintenance in cases of unemployment, industrial accident, illness, forced retirement, loss of a family breadwinner, or extreme deprivation, as well as various sorts of educational, preventive, and regulatory programs” (Orloff 1993, pp. 4–5). President Franklin D. Roosevelt’s New Deal policies, especially the Social Security Act of 1935, are regarded as the inauguration of the modern social welfare system in the United States. Social scientists and historians tend to have a much more expansive view of welfare than that put forth in the popular media, which associates welfare with certain types of aid to the poor. From the 1950s to the 2000s, scholars have been concerned with explaining both the origins of social welfare systems and the substantial variation in its form among advanced industrial countries.

**THE EMERGENCE OF WELFARE STATES**

An early and influential approach to understanding the origins of welfare states argued they emerged as part of the “logic of industrialism.” That is, scholars such as Harold Wilensky and Clark Kerr, among others, stressed that complex societies require a modern social welfare system in order to ensure a healthy, well-trained workforce and care for retired workers. Scholars criticized this view on a number of grounds. For example, in *Protecting Soldiers and Mothers* (1992) Theda Skocpol noted that in some places welfare provisions predated industrialization. In addition, Skocpol and other scholars such as Gösta Esping-Anderson noted that the logic of industrialism approach failed to explain the variation among welfare state systems.

Another group of scholars emphasized the humanitarian or idealistic motives for the expansion of welfare programs in the 1960s. This perspective argued that President Lyndon B. Johnson and other proponents of the Great Society programs implemented these policies and programs in response to the needs of the poor and oppressed. In *Regulating the Poor* (1971) Frances Fox Piven and Richard Cloward criticized this view, emphasizing that political and economic elites were primarily concerned with controlling the poor, not helping them out of poverty. Through an historical discussion of early reform efforts in England and the New Deal era in the United States, Piven and Cloward noted that welfare relief expanded during times of crisis so as to quell social unrest and then was retracted after the crisis was averted.

**THREE WORLDS OF WELFARE CAPITALISM**

Whether or not and to what extent elites could roll back welfare provisions depended, according to Esping-Anderson, on the strength of political class coalitions. In his *Three Worlds of Welfare Capitalism* (1990), Esping-Anderson argued modern welfare state systems emerged in response to the political class coalitions of workers and farmers in the late nineteenth and early twentieth centuries. Then welfare states expanded or contracted depending on the strength of the coalition of the working and middle classes. These political class coalitions sought state policies that enabled individuals to live outside the demands of the market, what Esping-Anderson termed *decommodification*. For example, workers have historically organized to demand unemployment compensation, pensions, health care, and other programs. These provisions enable individuals to exist without having to work. This improves the quality of life for workers and enables them to demand better work conditions from their employers.
Furthermore, welfare states in advanced capitalist countries display significant variation in the levels of decommodification each system provides for its citizenry. In fact, Esping-Anderson argued they can be grouped together into what he called three worlds of welfare capitalism: the conservative (e.g., Germany), the liberal (e.g., United States), and the social democratic (e.g., Sweden).

For example, in liberal welfare regimes, such as the United States, working class movements and parties have been historically weak. In these countries workers were unable to forge durable coalitions with farmers and later with the new middle classes. As a result, the welfare system in liberal regimes is relatively small and dualistic. That is, instead of a universal system where everyone benefits from welfare policies and programs, it creates two segments in society: one group receives benefits based on their tax contributions while a second group receives benefits regardless of whether or not they pay into the system. In the United States, social security and unemployment insurance are considered contributory entitlements. For most workers, a portion of each paycheck goes toward funding these programs. The second group of welfare recipients is comprised of those who receive aid without making a contribution. This type of aid is means-tested; that is, recipients have to demonstrate they qualify for relief and have to submit to government surveillance, else forfeiting the aid. In addition, in this dualistic system recipients of entitlements (e.g., Social Security) are not stigmatized while those who receive non-contributory aid (e.g., Aid to Families with Dependent Children [AFDC]) are heavily stigmatized. This stigma is supposed to provide a disincentive to receiving aid. For Esping-Anderson decommodification in liberal welfare regimes is low.

In conservative welfare regimes, such as Germany, working class movements are stronger and successfully forge coalitions first with farmers and later with the middle class. However, all social policy is cast in the light of Catholic ideals of tradition and stability. Emphasis is placed on maintaining the traditional family, with a male breadwinner and female homemaker. Thus decommodification is higher than in liberal regimes; yet feminists have pointed out that conservative regimes maintain a subordinate role for women.

In social democratic welfare regimes, such as Sweden, working class movements are strong and successfully forge alliances with farmers and the middle class. Thus for Esping-Anderson decommodification is the highest in social democratic welfare regimes. In these countries, taxes are relatively high, and instead of a dualistic system, benefits are granted on a universal basis, thus preventing the negative consequences of dualism and assuring continued support from the middle classes.

MODERN INTERPRETATIONS

Feminists such as Skocpol have criticized class-based explanations of welfare state systems for failing to take seriously the role of state managers in the production of social policy. Skocpol argued that class-based scholars have emphasized the role of working class (male) movements in provoking the rise of welfare states. As such, they have offered an explanation of the so-called paternalist welfare state. Skocpol argued that in the United States a maternalist welfare state predated the paternalist one.

Skocpol found that the earliest efforts at social provision focused on taking care of Northern Civil War veterans in the late 1800s. This was an early and important form of old age pension. In addition, she traced the efforts of early feminists who played key roles in gaining pensions for women and policies that helped children in the early twentieth century. These feminists successfully influenced the creation of a welfare state that sought to protect soldiers and mothers.

Linda Gordon studied many of the same early feminists as Skocpol and offered important insights into maternalist welfare states and the origins of welfare in the United States. In *Pitted but Not Entitled* (1994) Gordon argued that feminists played key roles in agitating for and making governmental policy, noting that early welfare policies sought to reinforce traditional understandings of femininity, especially those that emphasized homemaking and caregiving. Thus the maternalist policies aimed at “protecting soldiers and mothers” were also paternalist, premised on the idea that men should work and women should be subordinate to them, taking care of the housework and the children. Moreover, Gordon demonstrated how welfare policies of the early twentieth century emphasized care for white women who were married with children. Single mothers and women of color were excluded from policies that were designed to complement the “family wage” earned by male husbands/workers. As such, the role of welfare aid was to help maintain the integrity of the traditional white family without usurping the role of male breadwinner. However, a substantial number of male workers had a very hard time earning enough money to support their families, a situation even more pronounced for single mothers.

In addition, Gordon maintained that New Deal welfare policies did more to help the nonpoor than the poor. Policy makers restricted the kinds of jobs that could contribute to Social Security and unemployment insurance. Due to the kinds of jobs they had, such as in agriculture or as domestic help, most women and blacks, for example, were not eligible for these benefits. This gendered and racialized nature of early welfare policies in part reflected the power of southern elites who influenced social policy so as to maintain a loose agricultural labor market in the
South. As a result of concerted political behavior of southern elites, the New Deal welfare policies were enacted unevenly in the South, if they were enacted at all. In the South, welfare provisions were meager, while in the industrialized North they were more generous.

This point is expanded upon by Jill Quadagno, who studied welfare policies from the New Deal through President Johnson’s Great Society programs of the 1960s. In *The Color of Welfare* (1994), Quadagno showed how the Great Society programs sought to incorporate blacks and other minorities into the welfare state for the first time. However, such efforts resulted in a conservative backlash that pushed for a retrenchment of welfare to deny blacks an equal footing in society. This retrenchment, inaugurated by President Jimmy Carter, became a key platform of President Ronald Reagan, and was capped off by the signing of President Bill Clinton’s “End Welfare as We Know It” bill in 1996, which ended the U.S. government’s commitment to providing a safety net for the poor. The 1996 welfare reform bill transformed the pivotal AFDC program into TANF (Temporary Assistance to Needy Families), premised on the belief that instead of aid the government should provide inducements to work. Under these so-called workfare programs, there is a lifetime limit of five years of support, recipients must find work within two years or perform free community service, unmarried mothers must identify fathers to receive aid, and immigrants as well as unmarried teen parents are denied access to welfare programs.

**SOCIAL WORK**

Social work is a both an academic discipline and a profession. The discipline of social work teaches theory, methods, and practice of the profession. Like many other disciplines within the social sciences, social work studies human behavior in a social environment. Social work is also a practice where individuals can work with individuals, families, groups, organizations, and communities in various settings, such as schools, hospitals, mental health clinics, domestic violence shelters, senior centers, elected offices, private practice, advocacy organizations, and a host of other public and private agencies. The ultimate goal of social work is to enhance the well-being and level of functioning for all people and to create positive social change by improving social conditions and creating more humane practices and policies for vulnerable populations.

Despite the overlap among social work, sociology, and psychology, there remain distinct differences between the disciplines. Social work seeks to intervene between people and their environments. Further, social work addresses social and economic conditions that affect individuals, families, groups, organizations, and communities and highlights the importance of a multicultural understanding of both people and communities. Sociology is an academic discipline—not a professional activity—that studies social groups, organizations, institutions, and societies. Psychology studies and treats individual behavior and mental processes.

Social work is driven by various ideological perspectives. The three most prevalent ideologies are conservative, liberal, and radical. The conservative ideology within social work focuses on a microlevel analysis of the individual, and the primary goal is to assist an individual and perhaps a family with their individual difficulties. This view holds the individual and family responsible and embraces private over public solutions. A liberal orientation in social work holds that social and institutional arrangements affect individual and societal well-being. A liberal view holds that government intervention is crucial and that a private response is insufficient: Government should provide a safety net, according to liberal ideology. This focus is typically considered a mezzo-level analysis. Lastly, the radical tradition of social work adopts a macro focus that confirms the need to restructure social, political, and economic institutions so they may provide a more equitable, universal, and democratic system. This radical view can be critical of the profession, most often targeting the conservative view as reproducing societal inequities and abandoning the historical roots of social work. Further, the radical tradition within the profession has been critical of social work practice as being tied to the state apparatus, which ultimately perpetuates poverty and inequality.

Ideological tension within the profession has historical roots, and there continues to be conflict today about the relevance and effectiveness of micro versus macro practice, although contemporary social workers have
begun to recognize that what makes social work unique is the ability to locate social problems within the complex interconnectedness of individuals, families, communities, and societies. This multiple perspective of understanding social problems is one of the profession's assets.

Another view of the social work profession offers poignant criticism. Many authors have addressed the unique quandary that social workers face given the complexities of the U.S. social welfare system and its relationship to capitalist ideology and institutions. In Frances Fox Piven and Richard Cloward's seminal work *Regulating the Poor* (1971), they highlight that social welfare does not curb capitalist institutions; instead, it supports and enhances them. Moreover, the social worker is often the vehicle to ensure capitalism's survival. The profession must deal with this contradiction spelled out by Piven and Cloward, along with others, whereby social workers work in and are committed to the very institutions and agencies that perpetuate inequality, yet social workers rely on these same agencies for their livelihood.

As the various ideological perspectives of the profession reveal, there are numerous and varying accounts of the social work profession. In sum, many believe the profession to be driven by altruistic and humanistic motives, whereas others focus on the history's middle-class do-gooder who seeks professionalization. Still others describe social work as a profession that exerts social control over the poor, further legitimizing capitalism. In fact, social work's historical development embodies each of these realities.

**HISTORY OF THE PROFESSION**

The profession of social work dates back to the mid-1800s, when state charities began and institutions were established to deal with dependent populations such as the mentally ill, poor children, and people with disabilities. Prior to state intervention, mostly local churches and philanthropic organizations attempted to tackle social problems. But by the end of the nineteenth century these state-run institutions were failing and no longer providing quality care. Simultaneously, two movements emerged offering new ways of dealing with the poor and vulnerable in society: Charity Organization Societies and the Settlement House Movement. Each of these movements, both of which had roots in England, had approaches of dealing with social problems that embraced an ideological stance. The former adopted a conservative view, whereas the latter embraced a radical ideology that confirmed the need for fundamental social change.

Abraham Flexner (1866–1959), an educator who was considered an expert in evaluating professional standards and advocated for radical change in the way that medical schools trained doctors in the United States and Canada, said in 1915 that social work had not yet achieved professional status due to its lack of professional standards. Flexner was the author of the famous *Flexner Report* (1910), which had argued for increased standards in medical schools. He concluded that in order to be considered a profession, social work, like medicine, must have its own set of skills and specialized education that is based on scientific knowledge. Social work used this conclusion as an impetus to create and expand the types of setting for social work practice and paid attention to developing a knowledge base that was unique to social work. As a result of new practices, partly driven by the expansion of social welfare provisions in the 1930s, social work became acknowledged as a legitimate profession.

During the Great Depression of the 1930s the field witnessed an expansion in both the number of social workers and the type of work they did. Social work played a crucial role in helping shape and develop the United States's first institutional welfare program. In fact, a notable social worker, Harry Hopkins (1890–1946), headed Franklin Delano Roosevelt's emergency relief program, and another social worker, Jane Hoey (1892–1968), was the head of the Federal Bureau of Public Assistance. Since the 1930s social workers have been central in organizing and running governmental programs that aid the poor and needy.

After the New Deal and Social Security Act were passed, public perception about the profession of social work became more positive, and social work practice expanded greatly. Professional standards increased as well as academic requirements. Given the proliferation of services available to the public, the numbers in the profession increased greatly during these years. Social workers had a renewed sense that social reform was fundamental to their mission. From the 1940s to the 1970s social work was a growing field, expanding into many new arenas and continuing its professionalization project. The 1980s and 1990s were difficult for the social work profession, with massive government cuts to social spending and social welfare services. New social problems emerged that posed new challenges to social workers, such as high rates of incarceration, HIV/AIDS, and the crack epidemic. Some social problems that had been around for centuries—homelessness and domestic violence—increasingly became more politicized and addressed. The 1990s brought decentralization, whereby the federal government assumed less responsibility for the poor and needy, and states were required to do more to respond to vulnerable populations. This historical shift had implications for the social work profession, such as less federal funding and less support, and, as a result, social workers have had to continue developing creative alternatives to remedy social problems.
SOCIAL WORK EDUCATION
Social workers can be trained on a bachelor’s (BA or BSW), master’s (MSW), or doctoral level (PhD or DSW) of education. Each level produces a specialty of knowledge and depth of skill. Bachelor-level social workers are typically referred to as “frontline workers” who adopt a generalist orientation to social problems and who work in fields ranging from child welfare to domestic violence to services for the aging. Masters-level social workers are also educationally trained as generalist practitioners, but they receive additional training in a particular field such as clinical practice; children, youth, and families; gerontology; substance abuse; public policy; and not-for-profit management. Doctoral-level education in social work provides students with all of these, as well as training to assume leadership positions in agency work or to become faculty members at colleges and universities. In 1952 the Council on Social Work Education (CSWE) was established to oversee curricula within schools of social work. The council is the accrediting body of schools of social work on both the bachelors and masters levels.

SOCIAL WORK’S PUBLIC IMAGE
Today there are approximately 600,000 people who hold social work degrees. According to the Bureau of Labor Statistics, social work is one of the fastest-growing careers in the United States. Given this rise, the profession has received increased public attention, both positive and negative. Public perception of the profession is often misinformed. According to the 2000 census, 845,000 individuals self-identified as social workers. Many individuals who work in the field of human services identify themselves as social workers, yet they do not have any formal social work education. This contributes to the misinformation about the profession’s scope of work, and the educational training required by schools of social work. Many states have passed legislation to protect the title “social worker,” restricting it to those who have completed a social work degree from an accredited institution of higher learning.

In 1955 the National Association of Social Workers (NASW) was formed. NASW is the largest membership organization representing professional social workers. It “works to enhance the professional growth and development of its members, to create and maintain professional standards, and to advance sound social policies” (National Association of Social Workers 2006).

Social work is a complicated profession. Like sociology and psychology, there are competing views and traditions, ranging from conservative to liberal to radical, each of which embraces a different ideology and set of practices. Social work has a long and rich history, becoming institutionalized in state programs and during the New Deal in federal programs. Today, there are nearly one million social work professionals in the United States practicing in nearly every setting. Social work’s growth is likely to continue, producing positive outcomes in the lives of individuals as well as institutions.

SOCIALISM
Socialism can be defined as a political ideology that endorses the equality of power. Socialists believe that the existence of unequal material relationships is evidence of unequal political and social power in any given society. The goals of all socialists are the same: collective living and working arrangements, equal distribution of wealth, and equality of power. The attainment of these goals would guarantee a moral human society with happiness, equality, brotherhood, and community as foundational values.

The methods used to attain these goals have differed according to unique historical circumstances. Some socialists have endorsed industrial efficiency, while others have argued for a return to a “primitive,” nonindustrial stage of human history. Additionally, certain socialists have valued...
organization, control, discipline, hierarchy, leadership by experts, compulsion, violent revolution, and messianic elitism over gradual change, democratism, and pacifism to develop a socialist society. Socialists have sometimes appealed to nationalism and patriotism to recruit supporters. Other times they have proposed a more cosmopolitan philosophy of human organization. The role of the state has often been at the heart of these contradictory approaches. Some socialist states have created dictatorial governments to destroy traditional society and replace it with a pseudosocialist one. Other socialist movements have called for the creation of a just welfare state to take the primary responsibility for providing adequate housing, health care, pensions, and unemployment benefits to all citizens. Alternately, Communists have worked to eradicate the state apparatus entirely, instead offering a purely democratic structure of power relationships.

HISTORICAL EXPLANATION FOR THE RISE OF SOCIALISM

The formulation of socialism as a political ideology occurred between 1815 (the end of the Napoleonic era) and 1848 (the publication year of Karl Marx’s Communist Manifesto and a year of liberal, nationalist revolutions across Europe) as a particular response to the French Revolution and the Industrial Revolution. The French Revolution of 1789 began the slow destruction of the ancien régime in Western Europe and ushered in the modern period of liberal democracy and industrialization. During this process, the bourgeoisie replaced the aristocracy as the dominant social class, and as the abolition of serfdom swept across Europe during the Napoleonic Wars, European peasants left the villages and migrated to the cities to work in the new industries of the nineteenth century. The population of European cities exploded during this era of urbanization, and the new industrial working classes suffered tremendously from horrid living and working conditions.

The “dual revolution,” as the simultaneous liberal and industrial revolutions of the nineteenth century are called, created a social, political, and economic system that destroyed the traditional identities of Europeans, a system that had been founded on values of community, and instead legitimized an individualism that favored white, male property owners. The promotion of a minority of the European population at the expense of the workers, peasants, and women of all social classes angered socialist intellectuals, who criticized the failure of liberal democracy to extend fundamental human rights to all peoples. Though professing that liberalism would bring about progress in Europe through the destruction of legally defined social groups and the introduction of the right to vote, the right to free assembly, an end to censorno ship, equality before the law, social mobility, and economic freedom, socialists charged that liberal democracy merely created a new bourgeois-dominated social hierarchy that exploited the working classes for personal gain. They saw the liberal promise of economic freedom as a dangerous one because it guaranteed only workers’ rights to sell their labor to the highest bidder, and since wages in a capitalist system are tied to market forces, industrial society justified its exploitation of workers as being a kind of natural economic state. Socialists thus viewed liberal capitalism as an immoral system.

Liberal democracy and socialism in the nineteenth century were therefore antithetical: Whose rights should be protected—those of the bourgeoisie to possess private property or those of the working classes against the vagrancies of capitalism? At the heart of this dispute were differing ideas of the intrinsic goodness and value of private property. Liberal capitalists viewed private property as the most sacred of all human rights, while socialists viewed it as the root of all evil in the modern world. Another controversial debate was the natural state of humanity: Is communal organization the foundation of natural law? Can and should we use some definition of natural law to judge existing social institutions? Early nineteenth-century socialists agreed with Enlightenment thinker Jean-Jacques Rousseau (1712–1778), who argued that men are social by nature and naturally want to do and be good. Humanity therefore had the ability to return to this “natural” state through a process of purification. Rousseau also argued that the fall of humanity began with the introduction of private property.

Rousseau inspired the first French socialists, the egalitarians, who reacted violently to the fact that the French Revolution did not bring about social equality or abolish material wealth in the early nineteenth century. Egalitarians urged the people to seize power, do away with social hierarchy, and institute a commonwealth. They also advocated the use of terrorism to dispossess the wealthy and redistribute private property equally among all members of society. In this early stage of socialist development, the abolition of private property was not yet part of the political agenda and the goal was to end the misery of the poor. The egalitarians introduced the idea that the community was more valuable than individuals in isolation. Egalitarianism also endorses a pure democracy without party divisions. Service, devotion, and sacrifice for the sake of community were the hallmarks of egalitarianism.

Socialism took on a more organized form with the rise of utopianism in the 1830s. Charles Fourier (1772–1837), often referred to as the father of utopian socialism, argued that industrialization and liberal democracy did not constitute historical progress. He firmly placed the critique of bourgeois society in the greater context of the
rise of the materialization of humankind. Bourgeois society, he argued, reflected a fundamental departure from the foundation of human social life. Fourier rejected the progressive function of industry and technology and instead advocated for the creation of communal organization based upon agricultural units he called phalanstères. Along with this rejection of industrial capitalism, Fourier demanded minimum public regulation of individuals and a maximum level of individual freedom. Total gender equality, guaranteed by the destruction of marriage as a social institution, was also a major component of his philosophy.

Fellow utopian socialist Henri de Saint-Simon (1760–1825) rejected Fourier’s denunciation of industry and focused his critique of liberal capitalist society on increasing workers’ economic and political power, clearly defining socialism as an economic doctrine. Saint-Simon argued that order and efficiency were natural characteristics of humans. Since the interests of entrepreneurs and workers were identical—to increase political status through productivity—human beings would naturally agree to a collective social and economic construction once they realized how profitable such an arrangement could be. Private property, Saint-Simonians charged, was therefore incompatible with the efficiency of the industrial system. By transferring private property to the state, which would be controlled by an association of workers, privileges of birth would disappear. Additionally, the banking system, acting as a social institution, would coordinate the economy for the entire society. Saint-Simon also advocated for female emancipation and special care for paupers and criminals, all of whom he considered to be victims of the immoral bourgeois capitalist state. These radical changes would allow for the moral regeneration of society to occur. Fourier’s and Saint-Simon’s contradictory critiques of industrial society and visions of the future illuminated the controversial aspects of socialist thought in its early years.

The French utopian socialists greatly influenced German philosopher, historian, sociologist, and economist Karl Marx in the mid-nineteenth century. The Communist Manifesto, published by Marx and his partner Friedrich Engels in 1848, presented a theory of history in which an inevitable communist revolution led by industrial workers, the proletariat, would destroy bourgeois capitalist society. While utopian socialism in its various manifestations can loosely be defined as a worldview that promised individuals a full sense of belonging to a progressive communal society, Marx’s Communist theory at this early point in his career outlined a specific path toward the attainment of this goal. Marx viewed the history of mankind as being propelled forward by class warfare. He argued that human beings’ identities are defined by their economic relationships to one another, not by religion or other social constructs. The dominant social class, therefore, uses its political and economic position to exploit the subordinate social classes. The struggle between social groups, and the revolutionary attempts of the subordinate classes to destroy the ruling class, is what moves history forward. He called this process dialectical materialism.

In the context of nineteenth-century European industrial society, Marx forecast that the industrial proletariat would overthrow the capitalist bourgeoisie and the revolutionary cycle would end because, for the first time in history, the revolutionary class would represent the majority of the population. The revolution, Marx predicted, would occur on a worldwide scale as members of the proletariat in every industrialized country would spontaneously revolt. Industry would quickly spread to nonindustrialized portions of the world and all societies would become one large “workers’ paradise.” In the process, nations would cease to exist as primary determiners of an individual’s identity. The new communist system would guarantee total equality among all people through collective ownership of the means of production (such as land, machines, factories, tools, and animals), the abolition of private property, and collective living arrangements. The establishment of a complete democracy under such conditions would allow for the “withering away” of the state apparatus and the complete spiritual fulfillment of each individual.

The failure of the Paris Commune (1871) to install a socialist society in France prompted Marx to question this early assertion that a spontaneous and violent revolution was the only path toward socialism. In his later works, Marx tacitly acknowledged the possibility of a peaceful transition to socialism in those societies with mature democratic political systems. This move away from the notion that the excesses of liberal capitalism would naturally produce a proletariat revolution laid the foundation for democratic socialism to emerge as a Marxist political ideology in the late nineteenth century. This inconsistency in Marx’s philosophy of revolution allowed future communists and social democrats alike to claim him as the founding father of their radically different processes of revolutionary change. However divergent in their methods, atheistic socialist revolutionary movements around the world shared a common belief in Marx’s materialist interpretation of the human experience, one that charged religion with being the “opiate of the people” in the twentieth century.

**HISTORICAL EXAMPLES OF SOCIALISM**

Vladimir Ilyich Lenin led the world’s first socialist revolution in Russia in 1917. Lenin compromised the demo-
Supporters of the New Left of the 1970s and 1980s dedicated themselves to establishing just social, economic, and political domestic and international structures. The fall of the Soviet Union in the early 1990s effectively destroyed the dictatorial socialist model in Europe, with most European countries working to develop liberal capitalist societies that guarantee freedoms and rights for all individuals.

SOCIALISM, AFRICAN

There are two basic models of African socialism that represent its variations and development on the continent (Rosberg and Callaghy 1979). The first, more populist type refers to a “first wave” of socialist regimes that emerged during the early years of independence—from the late 1950s throughout the following decade. Flexible, pragmatic, and attuned to local conditions, these first socialist governments in Africa recovered the communalism of traditional culture after breaking free from colonial domination. The second leading model represents a “sec-
ond wave” of more militant regimes that consolidated power during the 1970s, favoring scientific socialism, an exclusive vanguard party, and a command-style economy while renouncing the false consciousness of traditional culture. These two models are of course abstractions and should not obscure the discrepancies between theory and practice, rhetoric and realpolitik, as well as principles and personalities found within each “ideal type.” If a populist-socialist such as Julius Nyerere (Tanzania) could force resettlement in Ujamaa villages (Khapoya 1994, p. 202), a vanguard Leninist such as Marien Ngouabi (Congo-Brazzaville) could protect French interests in phosphates and timber (Decalo 1979, pp. 258–259). Indeed, given that all African economies remain fundamentally mixed and export oriented, African socialism may well be more about the political manipulation of ideological resources than the public ownership of the means of production, particularly in the geopolitical context of the cold war. Nonetheless, the rise and fall of such powerful ideologies illuminates the broader historical forces that shaped African socialism and account for its different forms. One must begin with a discussion of the ideological origins of African socialism before moving on to its first and second “waves” of implementation.

**HISTORICAL ANTECEDENTS: THE GENEALOGY OF AN IDEA**

The mythic origins of African socialism are found in Victorian evolutionism, with primitive hordes, group marriages, and the glaring absence of private property representing the earliest stages of society. Ethnologists such as E. B. Tylor and Lewis Henry Morgan established unilinear pathways from savagery to civilization that reinforced the racial hierarchies of imperial ideology with blacks at the bottom and whites at the top. The influence of this evolutionary perspective was pervasive, informing Sir Henry Maine’s transition from status to contract in comparative law, Ferdinand Tönnies’s sociological distinction between Gemeinschaft and Gesellschaft, and of course the “primitive communism” of Marx’s pre-alienated man. When mapped onto the ur-terrain of the Dark Continent, a romanticized image of an original socialist Africa took shape, laying the foundation for the varieties of Pan-Africanism that developed in the first half of the twentieth century.

Edward Blyden (1832–1912) is generally acknowledged as a founding father of Pan-Africanism and its associated socialist traditions. Born in Saint Thomas and raised in Venezuela and the United States, Blyden moved to Liberia, where he advocated the repatriation of blacks to Monrovia. His ethnographic forays into West African hinterlands—commissioned by the British Crown—inspired such important works as *Christianity, Islam, and the Negro Race* (1887) and *African Life and Customs* (1908), in which he moved away from Christianity toward Islamic and indigenous frameworks for African government and self-determination. Of “pagan Africa” he wrote: “Social life … is communistic or co-operative. All work for each, and each work for all,” citing such proverbial wisdom as “What is mine goes; what is ours abides” (Blyden 1979, pp. 81, 89). Challenging Victorian myths of primitive savagery with utopian counter-myths of African socialism, Blyden’s stylized portrait of the continent would be refined in the writings of W. E. B. Du Bois (1939), Carter G. Woodson (1936), and in the Négritude of Leopold Sédar Senghor, all of which effected an important ideological transformation. Reworking the imperial opposition between civilization and barbarism, in which racial stereotypes between whites and blacks were largely preserved, Pan-Africanism reversed the hierarchy itself. The individualistic, hyperrational, industrializing societies and economies of the West were no longer signs of superior civilization but symptoms of profound alienation, expressed by the very separation of mind and body diagnostic of Western enlightenment. Africans, by contrast, were more “organic,” integrating mind and body, feeling and thought, and most importantly, self and community into collective forms of ownership and everyday life. Africa emerged as a positive foil against which the West was negatively recast, with its crime rates, rapacious greed, and growing inequality. The historical arrows were similarly reversed. Whereas the racist Hamitic Hypothesis of imperial discourse attributed the cultural achievements of Africa—such as political centralization or the invention of iron—to exogenous infusions of “Hamitic” or “caucasoid” blood, the Pan-African vision attributed Africa’s decline to the depredations of foreign conquerors and slavers who undermined the traditional fabric of economy and community. Identified and recovered, the socialist underpinnings of Pan-African culture would restore Africa’s rightful place in the world.

The Pan-African project took shape against the formal frameworks of European colonization at the turn of the twentieth century. The important Pan-African philosophies of this movement, including Léopold Senghor’s “Négritude” and Kwame Nkrumah’s “African Personality,” cannot be separated from the congresses and colloquia that brought together activists and intellectuals from Africa and the African diaspora. (One of the best comparisons of Négritude and African personality remains Irele [1990]). The four Pan-African congresses organized by Du Bois in 1919, 1921, 1923, and 1937 were framed primarily in terms of race, challenging the “color-bar” through Pan-African alliances that included British socialists such as Sidney and Beatrice Webb, Harold Laski, and H. G. Wells. But the fifth, so-called Manchester Congress held in 1945, reflecting the rising
influence of George Padmore, signaled an explicit shift toward decolonization, mobilizing Africans in discourses of trade unionism, socialism, and self-government. It also influenced the careers of Nkrumah, Azikiwe, and Kenyatta, who became icons of independent nationhood. Nkrumah went on to organize the Union of African States (1960) with Guinea and Mali joined by Morocco, Algeria, and Egypt to form the Casablanca group (1961) with a militant commitment to continental unity.

Thus formed a “militant wing” of the Pan-Africanist movement, countered by the more pragmatic Brazzaville and Monrovia groups seeking socialist solutions through economic regionalism. Tensions between militant and moderate socialisms; between national, regional, and continental priorities; between North African and sub-Saharan “cultural” divides; and between inherited colonial philosophical dispositions persisted within the Pan-African community, not only in the Dakar Colloquium (1962), where Senghor reasserted Négritude’s universalism, but also within the Organization of African Unity after it was founded in 1963. Nonetheless, a general model of “open” African socialism emerged (Senghor 1964), emphasizing state-directed public-sector development, trade unionism, marketing cooperatives, people’s banks, limited land reform, independence from foreign export markets, political mobilization through mass party organization, commitment to egalitarianism, and relative geopolitical autonomy based on the indigenous values of African cultural unity. Principlled autonomy from the Soviet Union was also a major theme of the Afro-Asiatic Bandung Conference in 1955, a conference considered by Senghor (1959, p. 3) as the twentieth century’s equivalent of the 1847 Congress of the Federation of Communists, which commissioned “The Communist Manifesto.” Pan-African in rhetoric, African socialism took root after independence within the political confines of the new nation-states.

THE FIRST WAVE: POPULIST-SOCIALIST REGIMES

It is difficult to separate the first socialist experiments in Africa from the charismatic leaders who brokered independence, such as Kwame Nkrumah in Ghana, Léopold Senghor in Senegal, Sékou Touré in Guinea, Modibo Keita in Mali, Amilcar Cabral in Guinea-Bissau, Kenneth Kaunda in Zambia, and Julius Nyerere in Tanzania. Nkrumah’s brand of socialism is hard to pin down as it shifted between nationalism and Marxism, public-sector development and multinational capital, respect for traditional socialist values and disdain for traditional “reactionary” chiefs, and finally, between the mass principles and exclusionary practices of its ruling Convention People’s Party (Apter 1972). Squeezing cocoa farmers through its extractive marketing boards, the state sought to underwrite industrialization and infrastructural development, but as debt increased and productivity dropped, the economy slid into a downward spiral. Fearing political conspiracies within and neocolonial enemies from abroad, Nkrumah became increasingly radicalized and isolated and was ousted by a coup d’état in 1966. In similar trajectories of socialist development and decline, Modibo Keita in resource-poor Mali and Sékou Touré of mineral-rich Guinea collectivized agriculture, nationalized banking, and blended Marxism with African cultural models. In both cases, peasant producers lost out in the reforms, and agriculture stagnated. Whereas Keita was overthrown by a coup in 1968, Touré, who died in 1984, gradually abandoned his socialist policies for Western economic investment.

The most extensive socialist project based on “African” principles was Nyerere’s Ujamaa villagization scheme, in what became the hallmark of Tanzania’s commitment to self-reliance. In Ujamaa: Essays on Socialism (1968), Nyerere offers a doctrine of traditional extended “familyhood” (ujuamaa) as a blueprint for African unity and development. Enshrined in the Arusha Declaration of 1967, this doctrine rejected heavy industrialization, with its dependency on foreign capital, in favor of collectively organized agricultural production in newly formed Ujamaa villages. What began as “voluntarist, grass-roots, cooperative socialism,” however, became “socialism imposed from above” (Young 1982, pp.114–115) as recalcitrant peasant producers in scattered peasant homesteads were relocated into cooperative communities. Dean McHenry (1979, p. 43) estimates that 91.3 percent of the rural population was living in ujamaa villages by 1976. Although villagization, combined with Scandinavian aid, improved education, medical care, and public utilities in the rural areas, an overall decline in peasant production, including severe food shortages in 1974, eventually brought the experiment to an end. Nyerere resigned in 1985 to make way for neoliberal reforms, but his legacy of national unity and the correlative absence of ethnic politics in Tanzania has endured.

THE SECOND WAVE: SCIENTIFIC-SOCIALIST REGIMES

If the first wave of African socialist states in the 1960s sought the recovery of cultural traditions (Senegal and Tanzania more than Ghana and Guinea), the scientific socialist regimes of the 1970s emphasized more radical ruptures—from the shackles of tradition, from colonial domination, and from preceding military juntas. Elevating a Leninist-styled vanguard party to control the state, these more centralized regimes used the language of class analysis in claiming peasants and workers as their social base, attacking incipient class formation, and
thereby justifying coercion in the persecution of political dissidents and internal enemies. In many areas, however, ideological principle was tempered by realism: If foreign owned banks and insurance companies were easily nationalized, more capital-intensive and productive multinationals were given freer rein as revenue-generating engines of growth. In geopolitical terms, greater solidarity with the Soviet bloc in the United Nations did not translate into firm Soviet trade relations and aid. Many of the Afro-Marxist regimes remained interested in Western capital investment, and thus economically nonaligned.

Crawford Young (1982) distinguishes military Marxist regimes from those that grew out of national liberation movements against Portuguese colonialism. Among the former, Congo-Brazzaville was the first to establish a Marxist regime in 1969, when Marien Ngouabi declared a People's Republic and inaugurated the Parti Congolais du Travail (PCT). Somalia followed under Mohammed Siad Barre in 1970, when Soviet military interests enabled Somali national consolidation within an enduring Islamic idiom. In the Republic of Benin, Major Mathieu Kerekou created the Leninist Parti Révolutionnaire du Peuple Beninois (PRPB) in 1975, developing new public corporations and peasant cooperatives without sacrificing economic relations with France. A more radical Marxist-Leninist state was implemented in Ethiopia by the revolutionary Derg ("committee"), a secret inner circle of the military who deposed Emperor Haile Selassie in 1975 and instituted major reforms, including the nationalization of land ownership and tendency to undermine the Amharic feudal aristocracy. Given its notorious “Red Terror” and rule through fear and intimidation, however, the Derg never secured popular legitimacy (Donham 1999).

Notable among national liberation movements were the protracted struggles in Angola and Mozambique against entrenched Portuguese settlers and political overrule that lasted until 1975. In Angola, a bloody civil war became a cold war battleground where a sizable force of Soviet and Cuban soldiers (20,000) and technicians (17,000) backed the Movimento Popular de Libertação de Angola (MPLA) against Jonas Savimbi’s reactionary União Nacional para a Independência Total de Angola (UNITA), supported by South Africa and the United States. (Angola’s political identification with the former Soviet Union still resonates from the hammer and sickle on its national flag.)

By the 1990s, the Leninist role of the MPLA degenerated into coveted disbursements of economic and political patronage based on control over oil and diamonds (Hodges 2004). In Mozambique, socialism developed through similar struggles against the Portuguese and, after independence, during a long civil war with South African-backed Renamo rebels. Samora Machel’s revolutionary vanguard party, FRELIMO, emerged as a highly disciplined organization supporting liberation movements in former Rhodesia and South Africa while promoting women’s rights, peasant collectives, state farms, and heavy industry at home. The dislocations of the civil war, however, and the atrocities of the Renamo fighters, exacted a heavy toll on the country and economy after a cease-fire was signed in 1992.

If socialism in Africa, like elsewhere, lost ground after the collapse of the Eastern bloc and the rising tide of neoliberal reforms, its central concerns have not withered away (Saul 2001). These remain the role of the state in regulating trade, the growing inequalities associated with economic liberalization, the political economy of “tribalism,” and the complex character of class formation in postcolonial Africa. Like the colonial heritage that it fought and opposed, socialism in Africa—even when disavowed—remains deeply embedded in the politics of national development (Pitcher and Askew 2006).

SOCIALISM, CHRISTIAN

In 1848 Karl Marx dismissed Christian Socialism as “the holy water with which the priest consecrates the heart-burnings of the aristocrat” (Marx [1848] 1967). His immediate, if unstated, target was the group of Anglicans around the theologian F. D. Maurice, who that year in London began a short-lived publication, *The Christian Socialist*. The occasion for their emergence—sympathy with Chartism—was political, and an important part of their activity was practical social witness, such as Maurice’s foundation of the Working Men’s College in 1854. Their Christian Socialism was thus reformist rather than radical and operated within a theological as well as a political context. As Maurice explained, he chose the term Christian Socialist to differentiate them from both “the unsocial Christians and the unChristian socialists” (quoted in Wilkinson 1998). The former were targets because of the pietistic emphasis on individual salvation of contemporary evangelicalism, and for political reasons. At the time Christian views of political economy were primarily shaped by emphases on responsibility: either in Malthus’s warnings about the demoralizing effects of the Poor Law or in the comforting commonplace of the time that he who pursues his own best interests is also supplying the interests of the community as a whole. Maurice attacked such views and the laissez-faire orthodoxy they reflected. Socialism for him, however, seems to have been largely about the church addressing the people inclusively rather than individually, not least through reformist social activity rather than the establishment of an alternative political economy.

Although the term *Christian Socialism* was popularized in this distinctive nineteenth-century context, it drew, as even Marx acknowledged, upon both biblical and ecclesiastical precepts. It may have been at this point that Christian Socialism began to emerge as a distinct witness, but those who followed in Maurice’s footsteps could associate their views with a much longer tradition. From the Old Testament the providence of land and the Jewish institution of Jubilee implied divine sanction of equal shares in the means of production and divine prohibition of private accumulation, while the prophets provided examples of denunciations of injustice. The New Testament furnishes strictures against the rich and the money changers, while Christ’s message that, instead of the love of self implied by such accumulation, people should love one another became, by the late nineteenth century, the basis for claims that Jesus was the first socialist. And the sharing of all things in common and their distribution according to need in the early church (Acts 2: 44–47; 4: 32–37) suggested protosocialist communities.

There were a number of attempts to re-create such communities in the early nineteenth century. Étienne Cabet in France saw the rise of the medieval church as having corrupted early Christianity, the ideals of which he sought to recapture in utopian communities. The non-Christian Robert Owen simultaneously experimented with such communities in Britain and America. Although his ideas were to influence Maurice, both his and Cabet’s communities ended in failure. Meanwhile, the shadowy League of the Just founded in 1836 and largely composed of German exiles in London was transformed from a body calling for the realization of the Kingdom of God on Earth through universal brotherhood in 1847 into the purported commissioners of Marx’s *Communist Manifesto*, which sought to achieve the ideal society through class struggle instead.

Some Christians accepted this diagnosis, while rejecting both the materialistic basis of Marxism and its facile assumption that an ideal society requires merely the expunging of class exploitation. They were, however, in a new situation, in which positivistic secular creeds sought to explain the human condition or express social ideals...

Andrew Apter
without necessarily having recourse to religious frameworks. Socialism could still benefit from the imprimatur of Christianity, but it could also become a rival creed to churches seen as more focused on salvation in the next world rather than this one. In continental Europe, as well, papal hostility to this challenge in Pius IX’s Syllabus of Errors (1864), as well as the extent to which Catholicism had become associated with defense of the established order, meant that nineteenth-century socialism there frequently had a distinctly anticlerical flavor. Despite the efforts of, for instance, Bishop Kettler of Mainz in the 1860s, this antipathy was not to be mitigated until after Leo XIII’s encyclical Rerum Novarum in 1891, which, while still condemning socialism, was much more open to labor organizations.

The more pluralistic political and religious culture of the Anglophone world produced different effects. An emphasis on the Incarnation and the corporate life of the church led Anglo-Catholics such as Stewart Headlam to revive Christian Socialism in the 1870s and 1880s. Walter Rauschenbusch’s emphasis in the 1890s on the Kingdom of God as an endeavor for this life, not the next, was also to have wide influence. It led to a positive view of state intervention. Contemporary economic and social developments, especially the emergence of more rigid class differences and secular socialist parties, were also prompting this trend. A “Social Gospel,” intended to bridge the gulf to the working classes by a mixture of social work in poorer areas and a generalized language of social welfare, appeared in both Britain and America around the end of the nineteenth century.

In America such figures as Washington Gladden emphasized a new concordat between capital and labor, not least through just wages and profit sharing. Meanwhile, in Edwardian Britain, the more radical idea of Guild Socialism came into vogue. This was an attempt to find ways for workers themselves to directly control their production and entrench the dignity of labor against the materialism of collective socialism. Grounded in part in medieval romanticism, practical expression was most nearly achieved by the guild organization in the building trades established by Quaker businessman Malcolm Sparks after World War I. Such ideas, however, did not long survive in the difficult economic climate of the interwar years.

Anglo-Catholic enthusiasm for a corporate and social expression in faith led instead to experiments such as the Christendom Group around Maurice Reckitt. Meanwhile, within the Roman Catholic Church, while the rise of Catholic Action as a means of engaging with modern conditions prompted a growing accent on social welfare by the 1930s, the theocratic nature of much of Catholic political thought militated against its being expressed in radical political ways. Exceptions included the Catholic Worker Movement founded by Dorothy Day and Peter Maurin in New York in 1933.

Significant change came with Vatican II in the early 1960s. In particular, its more active approach to pastoral care opened the way for political engagement. This was particularly true in Catholic Latin America, where popular protest against the extreme social inequalities of the Continent were already gathering strength in the wake of the 1958 Cuban revolution. Bishops meeting in Medellín in 1968 concluded that the Church had to be not only for the poor but of the poor. The focus, as developed in Gustavo Gutiérrez’s A Theology of Liberation (1971), was on God’s preferential love for the poor and oppressed, expressed, not least, by Christ himself identifying with their suffering on the cross. This perspective was subsequently to find wide application, particularly in the developing world.

Christian Socialism, then, is to some extent contextual and does not involve a single political or theological viewpoint. It has developed in relation both to secular socialist movements—some of which, like the British Labour Party, now have affiliated Christian organizations—and the wider churches. What is distinctive throughout, however, is the view that a more socially just society requires changes in people’s attitudes toward one another rather than simply in the social system.

SOCIALISM, ISLAMIC

Islamic socialism is a discourse that seeks to integrate Islamic spirituality and socialism, promoting religious
behavior, state ownership, and greater distribution of resources. Some of the most prominent examples of Muslim nation-states associated with the ideology are discussed below.

One of the first attempts was developed by Pakistani statesman Zulfikar Ali Bhutto (1928–1979) and the Pakistan People’s Party (PPP), who adopted the term in response to severe criticism from conservative ulama about their un-Islamic socialism. To help alleviate criticism, Bhutto often referred to the “equality of Islam” (Raza 1997). From 1971 he introduced a range of socialist populist policies aimed at greater redistribution of resources. Overall though, particularly after 1973, Bhutto failed to reconcile the differing expectations of his supporters and urban industrialists and rural landlords, and he became ideologically distanced from Islamic socialism (Noman 1988; Raza 1997; Syed 1992) until he was overthrown in a military coup in 1977.

Islamic socialism is most widely associated with Muammar Abu Minyar al-Qadhafi of Libya, who came to power in 1969. He had been heavily influenced by the leadership of, and Arab socialist nationalism expounded by, the Egyptian leader Gamal Abdel Nasser (1918–1970). Qadhafi sought to bring about political, social, economic, and cultural change. The Third Universal (or International) Theory was introduced and expounded in Qadhafi’s *Green Book*, which was published in three parts (1975, 1977, 1978). Qadhafi was critical of the excessive materialism and inequalities associated with capitalism, as well as communism’s atheism and stifling of individual development. His new doctrine was to be an alternative to the dominant metanarratives, and he incorporated elements of Arab nationalism, Islam, and socialism. The *Green Book* addressed perceived problems within liberal democracy, economics, and social relations. A number of key concepts and practices were promoted, including *Jamahiriya* (state of the masses), “popular democracy” through direct participation in congresses and committees (Qadhafi 1975, p. 25), state welfare, equity, and religious behavior and morals. Large-scale private ownership and opportunities for “exploitation” were restricted (El-Kikhia 1997; Monti-Belkouai and Riahi-Belkaoui 1996).

Since 1969, modernization processes have been implemented in Libya that have resulted in vastly improved communication and transportation networks and health and education facilities. However, the economy is overreliant on imports and oil revenues that have largely funded the advancements. Qadhafi’s regime has been widely associated with repression of political dissidents, armed interference in neighboring states, and international terrorism. Following the drop in oil revenues in the 1980s, the onset of trade sanctions, periodic shortages of basic goods, and political isolation, Libya’s economic and political policies were revised. Measures of economic liberalization have been introduced at the expense of Islamic socialist doctrine; these include privatization, expansion of public sector companies, and foreign investment, particularly after the lifting of United Nations sanctions in 2003.

During the 1970s, Islamic socialism, or scientific socialism as it was called by the regime, was also implemented by President Mohammed Siad Barre (1919–1995) in Somalia. Scientific socialism also sought to integrate religion and socialism and placed emphasis upon community development through self-reliance. But shifting alliances in the late 1970s contributed to closer ties with the West and a restructuring of debt that resulted in a loss of state macroeconomic control, greater liberalization, and the effective end of “scientific socialism.”

Today, Islamic socialism attracts little support. The inability of “Islamic socialist” regimes to deliver their promises contributed to the doctrine losing credibility and being replaced by political Islam as the “third way.”

BIBLIOGRAPHY

As a concept it generally embraced the idea of a nationalized economy embedded in a market.

The process began in 1952, when Josef Stalin’s *Economic Problems of Socialism in the U.S.S.R.* announced that a market existed in consumer goods. In the Soviet Union Professor Evsei Liberman (1897–1983) of Kharkov University put forward market-type proposals in 1962. These were taken up briefly by Alexey Kosygin (1904–1980) when he was the Soviet Union’s premier, but were dropped again in 1968. In Czechoslovakia the reform ferment under Alexander Dubček (1921–1992), the Communist Party secretary, led to proposal of a limited market in 1968. This was aborted by the Soviet invasion of that year. Poland and Hungary proceeded more slowly toward the introduction of market-type reforms. The final denouement came when Mikhail Gorbachev (b. 1931), general secretary of the Soviet Communist Party, passed a series of laws in the Soviet Union that were intended to introduce the market, beginning in 1986 with the Law on the State Enterprise.

For most economists market socialism ceased to have any meaning because the issue had been settled in favor of capitalism. The Polish economist Włodzimierz Brus and the Hungarian economist János Kornai effectively accepted capitalism. The concept, however, has continued to play a role in debates among Marxists and socialist theorists. Historically there were, and remain, two debates. The first concerns the possibility of the market being embedded in socialism. The debates in the U.S.S.R. and in other East European countries were variants of this question. The second concerns whether the market could coexist (or would be in conflict) with planning in a transition period to socialism. Nikolai Bukharin took the first view and Yevgeni Preobrazhensky the second. As an orthodox Marxist, however, Preobrazhensky rejected the view that a market (law of value) could exist in a communist society. At a 1924 debate on the subject in the Communist Academy, Ivan Stepanov-Skvortsov, the main speaker, appeared to argue for market socialism, but Preobrazhensky and Bukharin both opposed the concept very strongly, though they differed as above.

The Austrian Ludwig von Mises (1881–1973) argued in *Socialism: An Economic and Sociological Analysis* (1922) that calculation was impossible under socialism because value would be abolished. Oskar Lange (1904–1965), a Polish economist and later a member of the postwar Polish Communist government, took up the cudgels to argue that it was possible, writing in reply “On the Economic Theory of Socialism” (1936), as well as an essay with Abba Lerner. His argument hinged on a hypothetical pricing scheme worked out by planners, who in turn would base their studies on minimum costing. The idea that the market economy could be written into a series of equations, assuming equilibrium pricing, was already well established in orthodox economics. Lange was arguing that economic calculation was possible under socialism because it would plan as if it were a market economy. Lange was not a Marxist economist and therefore could not see that the essence of socialism, as perceived by Marxists, would be negated by this form of top-down “planning” because it involved control and discipline of workers by the planners. Leon Trotsky (1879–1940) writing at the same time argued that planning had to be democratic or else it would malfunction.

In a sense, Lange’s concept of socialism anticipated the later Soviet bloc reformers and their critiques. One of these was taken up by von Mises’s fellow countryman the Austrian Friedrich von Hayek (1899–1992), who pointed to the difficulty in calculating the millions of prices involved, a problem which the Soviet Union could not solve: At the time, the Soviet Union had 25 million prices that involved a huge process of calculation, given the interrelationships involved. Today Hayek would receive the reply that modern computing advances could solve the issue. However, few would want a central planner or planning ministry to decide all economic and social issues, even if computing would ensure consistency. In principle, computing could use either the Lange system of administered shadow prices or its own alternative schemes; that debate continues. Logically, in the interests of maximum control from below, there has to be a high level of devolution. The role of the market in a devolved economy is also a matter of continuing debate.

Alec Nove’s 1983 book *The Economics of Feasible Socialism* prompted a series of debates, most particularly with Ernest Mandel, in the *New Left Review*, and with others in the pages of the *New Statesman*. Nove argued that the central premise of a communist society—that it would be a society of relative abundance—was utopian, and hence it could not exist. Instead, it was necessary to adapt market forms and criteria to an economy with nationalized property. His book was a recipe for market reforms in the Soviet Union, and he later provided advice to the Soviet Union under Gorbachev.

The Soviet bloc countries of Hungary, Poland, and Czechoslovakia experimented with market forms, as did the Soviet Union. However, the reforms were always suspect among the working class, for whom they meant rising unemployment, greater inequality, and harder work, even if consumer goods were generally more available at lower prices. Reformers argued that the partial reforms were insufficient.

Departing from the classic case of market socialism, which presupposes an economy with most or all enterprises nationalized, but operating within a simulated or real market, the Scandinavian countries, Sweden in partic-
ular, generally have been regarded as successful examples of the coexistence of a large state sector and a developed welfare system, with a market economy. But the relatively high level of taxation and large state sector are regarded by some economists as responsible for lessening Swedish competitiveness in a global economy. The election in 2006 of a right-wing government that complained of a very high level of unemployment and promised to privatize and alter the taxation system seems to indicate a limit to the experiment. Debate continues on the reasons for the relative stability of the Swedish case.

The discussion on the role of the market, whether in the transition period to socialism or in socialism/communism, continues among Marxists. Debates around the subject of market socialism were held at the New York–based Socialist Scholars Conferences in the late 1990s and after. Most anti-Stalinist orthodox Marxists continue to maintain that the market will be abolished in socialism/communism. The difference among theorists as to whether the market is inimical to planning or whether it can exist in socialism/communism mirrors degrees of acceptance of orthodox economics.

SOCIALISM, NATIONAL
SEE *Nazism*.

SOCIALIZATION
Socialization is a concept that is studied in many different areas of social science and can be adequately explained by any number of disciplines. The general topic of socialization forms the backdrop for numerous lines of research in diverse academic areas such as anthropology, sociology, criminology, and all areas of psychology. The study of socialization differs according to academic domain. For instance, in sociology, socialization is studied in terms of groups of institutions where socialization occurs, whereas anthropology looks at socialization in the larger culture. In this entry, socialization is approached from a psychological perspective, focused on the development of characteristics related to social behavior in individuals.

The term *socialization* refers to the process by which people learn culture, roles, and norms in order to function within a society. The socialization of culture includes learning the language, beliefs, and social structure of the culture in which an individual lives. The socialization of roles includes providing structure and instruction as to how to act in different situations individuals are likely to encounter within their culture. Finally, socializing group norms refers to learning the expected and appropriate behavior in a society in order to productively interact with others. Each of these three elements is integral to successful participation in society.

Though socialization is essential to functioning in society, it sometimes may have negative consequences. Some socialization experiences induce conformity and discourage independent thought: An example of this occurs in certain religious cults where conformity is encouraged and dissent is viewed harshly. Another example of the negative consequences of socialization is the internalizing of various stereotypes. Regardless of whether the socialization experience encourages conformity or independent thought, the end goal is to have individuals who are able to successfully interact within a given society.

Socialization occurs throughout one’s lifetime, but it is particularly important during childhood, when the child’s personality is taking shape. In early childhood children are socialized to learn the fundamentals of language and culture, which will affect behavior and outcomes throughout their lives. In addition, the way children are socialized and what behaviors are learned as appropriate and acceptable affect personality development with consequences that affect their entire lives. But socialization continues throughout one’s entire life as new roles are undertaken and expected behaviors in each role are learned.

In many cultures, women are the first socializing agents in their capacity as the infant’s primary caregiver. Primary caregivers of infants and young children have the unique task of socializing the child into the culture and society in which the child lives. These caregivers often are influential in teaching acceptable behaviors and rules as well as fundamental skills such as language development.
Beyond the primary caregiver, the family as a whole has a large role in socialization. This venue is the first social structure for the child, and much social behavior is learned in this arena. As the child develops, teachers, schools, and peer groups become important socializing agents. Mass media also socializes throughout the life span, and religious influences are also important. Each of these domains is somewhat controlled by the family. Family influence on children's neighborhoods and peer groups affects what types of socializing agents the child has access to. On a wider level, each of these domains is influenced by the government. The government exerts influence on socialization through creating experiences common to all children, such as schooling. In this domain, government has a powerful role in determining what can and cannot be learned, thus implicitly socializing the child to what things are and are not acceptable. Through the creation of laws and enforcement of acceptable behaviors, government also affects the family; for example, by enforcing laws that state that parents are not permitted to physically harm their children, the government dictates what types of behaviors children are subject to and, more generally, what types of behaviors are desirable and undesirable in society.

Research has suggested that socialization is not a unidirectional phenomenon. In reciprocal socialization parents socialize children and children in turn socialize parents. Children act as socializing agents to parents in a most basic sense as parents must be socialized to the parent role—infants demand certain care and have fundamental needs of their parents. In addition, various outside influences act on children in ways that affect parents and change their behaviors as well. For example, schooling may affect parental behaviors by placing increasing demands on children which parents must accommodate. In addition, increasing peer influences may require parents to modify strategies and behaviors in interacting with their child. Individual characteristics of children, such as their levels of attractiveness and temperaments, may also be factors in the socialization of parents. Newly arrived immigrant families provide a clear example of reciprocal socialization. Parents in these families may learn much of the new country's language and culture from their children as the children have more opportunities to learn (e.g., in school) and are more able to learn new expected roles. In this way, children socialize parents to new roles, and parents socialize children in basic behaviors.

**MECHANISMS**

Socialization occurs through a variety of mechanisms, both directly and indirectly. Direct socialization occurs through the formal teaching of behaviors and includes reinforcement of accepted behaviors. Schooling, an important source of direct influence, is very controlled: Roles are highly defined and behaviors are explicitly taught and reinforced. Direct socialization occurs throughout one's life. In professional socialization individuals are explicitly taught new behaviors and accepted patterns of social interaction. Although socialization during childhood provides the backdrop for which individuals can successfully maneuver within society, as people age, their socialization becomes more specialized as they learn how to act in specific social situations and be successful in specific arenas.

Indirect socialization, on the other hand, is more informal. This type of socialization may occur anywhere and at any time. Noting what behaviors are successful for others and then imitating these behaviors is an example of indirect socialization. By providing access to situations and restrictions from other situations, socializing agents informally affect what roles and behaviors are learned. Through this method, children are not explicitly taught about acceptable behaviors, but nonetheless are socialized to them.

The psychologist Albert Bandura proposed a theory often used to understand socialization experiences, advocating a social-learning approach in which children learn social behaviors via a variety of ways. Children learn through observational learning of others' behaviors and through modeling these behaviors, as well as through reinforcement. This reinforcement can be directly given to the child, or the child may learn through vicarious reinforcement, in which another individual is observed to be rewarded or punished for behaviors; through this process the child learns which behaviors are acceptable and which are not.

In both direct and indirect methods of socialization it is important to note that socialization is a process both of learning and of being taught. Both experiences are important socializing influences. The process of learning emphasizes the active role of children, who must make sense of their social world in active ways that allow them to explore possible avenues of behavior. In addition, children have individual traits that affect socialization such as temperament, which predisposes each individual to different types of socialization and socializing agents.

Different factors have been found to affect the effectiveness of socialization. Two often studied factors are attachment to parents and parenting style. Attachment theory suggests that infants' relationships with their caregivers form working models of relationships in general that in turn affect children's understanding of the world and their interactions within social arenas. How children form these attachment relationships is an important factor in socialization in that it is through these relationships that they indirectly learn how to behave in the world.
Socialization

interpersonally and to form expectations about other people. This process provides an important source of experience upon which children draw to learn to act within their social worlds.

Diana Baumrind (1967) studied parenting style in terms of two dimensions: demandingness and responsiveness. She initially proposed three parenting styles: authoritarian (demanding but unresponsive parenting), authoritative (demanding and responsive parenting), and permissive (not demanding but responsive). Maccoby and Martin (1983) later added a fourth category, neglectful, encompassing parenting styles that are neither demanding nor responsive. In relation to socialization, parenting styles influence the methods by which the parents socialize their child and the effectiveness of the messages parents attempt to transmit. The emotional climate that is created through parenting style affects how children receive messages and how they are interpreted.

EFFECTS

Socialization has many effects on individual behavior and personality. First, it is integral to forming personalities in children. The very nature of socialization dictates that some beliefs and attitudes are reinforced and that there is only selective exposure to other possible attitudes. Children are thus given a set of acceptable behaviors and attitudes from which to form their personalities, creating a firm boundary of possibilities for personality formation.

Children also learn values through the process of socialization. Different sources of socialization including parents, teachers, and the media all have influences on what values the child learns are important. For example, from watching various sources of media in western cultures, most children learn that physical appearance is highly valued, and they mirror this belief in their own value systems. These influences provide the lens through which children view their social world and shape how they will continue to view the world into adulthood.

Socialization processes also affect the developing child through the learning of social and automatic biases about individuals and groups of people. As a part of socialization, children may learn what behaviors are expected and acceptable for different groups of people and may thus form stereotypes about these groups; a common set of stereotypes formed in this way are gender stereotypes. Through these socialization processes the roots of various psychological phenomena studied in social psychology, such as in-group biases, may be found.

TYPES OF SOCIALIZATION

Socialization is often studied in relation to specific roles that individuals take within society. Two primary examples of this line of research are gender socialization and racial socialization. The term gender socialization refers to the process by which children learn expectations of behavior for males and females. In children, gender socialization begins through differential treatment based on sex. Boys and girls are treated differently by important adult socializing agents according to what is considered to be acceptable gendered behaviors. Social learning theory is often applied to gender socialization as children are seen to be rewarded and punished for acceptable behaviors, and because they imitate same-sex gender models. This theory posits that children are passive recipients of these messages, but evidence suggests that children selectively and actively process the information they choose to imitate. A more active theory of gender socialization, gender schema theory, posits that children actively form cognitive sets of ideas about gender that help to organize information within their social world.

Racial and ethnic socialization refers to the transmission of messages about how different racial groups fit within society and the relationships between different racial and ethnic groups. Racial socialization is heavily emphasized within some families and in other families it is not considered an important aspect of socialization. As a part of this process, children are taught what behaviors to expect from others based on the race or ethnicity of individuals the child encounters, and they are taught various strategies with which to respond. Racial socialization is directly related to the racial identity that an individual adopts as he or she ages.

SOCIALIZATION OF INVESTMENT

The idea of socializing investment was introduced in 1936 by John Maynard Keynes in his *General Theory of Employment, Interest, and Money*. In the concluding chapter of the book, Keynes identified three major tasks to be undertaken in order to save capitalism from its own demise: “parting with liquidity,” “euthanizing the rentiers,” and socializing investment. The three are inevitably interrelated in Keynes’s theory, as he argued that effective demand is the engine of the capitalist economy and that spending by consumers, firms, and the government is what keeps the economy going.

According to Keynes, economic agents operate in real historical time under conditions of uncertainty in which the future is unknowable and the past is unchangeable. Faced with such an environment, individuals make arbitrage decisions with regard to which asset they wish to hold over time. Each asset gets a return composed of four components: $q-c+l+a$, where $q$ is the expected yield, $c$ is the carrying cost, $l$ is the liquidity premium, and $a$ is the appreciation or depreciation.

At equilibrium, all assets earn the same expected return. If an asset has a demand price higher than its supply price, then firms will produce more of it, but as its production increases, its return will fall and becomes equal to the returns of all other assets. When consumers and firms are optimistic about the future and feel confident about their financial situation, the expected returns on capital equipment rises above the expected return on money (the interest rate), which leads to an increase in investment, thus boosting output and employment. Conversely, when the economy is overtaken by pessimistic expectations, consumers and firms prefer to remain liquid, thus abstaining from spending on consumption and investment goods, which leads to a rise in unemployment.

According to Keynes, this is due to money’s very specific nature as the most liquid asset in the economy with a near zero elasticity of production, small elasticity of substitution, and no carrying cost. In other words, when people want to hold more money (liquidity), no significant amount of labor is directed to producing it (unlike, for instance, capital equipment).

Therefore, Keynes’s conclusion was that an environment must be created that is conducive to more investment and less hoarding of money. Hence his three policy recommendations: (1) “parting with liquidity” (giving up liquid assets in exchange for employment-creating illiquid assets); (2) “euthanizing the rentiers” by lowering the interest rate so much that nobody will find it profitable to save money (because expected returns on money are less attractive than expected returns on capital); and (3) socializing investment through the creation of a new kind of capitalist culture of cooperation between private and public authorities.

Keynes’s overall preference for discretionary fiscal spending led many to misunderstand his use of the term socialization of investment, despite the fact that Keynes made it very clear that he did not mean “socialism.” Keynes explained that socializing investment does not require that the government assume ownership of the means of production and dictate the terms of economic activity to the rest of the economy. According to Keynes, “[i]t is not the ownership of the instruments of production which it is important for the State to assume. If the State is able to determine the aggregate amount of resources devoted to augmenting the instruments and the basic rate of reward to those who own them, it will have accomplished all that is necessary” (Keynes 1936, p. 378).

Furthermore, Keynes emphasized the fact that the socialization of investment does not conflict with the basic features of capitalism. He repeatedly stressed the importance of protecting individualism, private property, freedom of choice, and competition. According to Keynes, the socialization of investment calls for no revolution—it is, rather, a gradual adjustment between the propensity to consume and the inducement to invest for the sole purpose of ensuring an adequate level of effective demand that is consistent with full employment.

The policy framework that is closest to Keynes’s idea of socializing investment is to be found in the Swedish (corporatist) model developed after World War II by trade union economists Gösta Rehn and Rudolf Meidner, who envisioned two essential elements that would characterize the Swedish economy for more than four decades: (1) highly centralized wage bargaining; and (2) active labor market policies. The model focused on the socialization of investment and offered a practical alternative to welfarism by putting a strong emphasis on “the right to work” rather than “the right to income.” The model strongly encouraged private investment despite high tax rates on profits. Firms were allowed to put their “excess profits” into tax-exempt “investment funds,” thus encouraging capital accumulation. Under this model, Sweden was able to keep...
its unemployment rate below 3 percent for decades without any significant inflationary pressure.

SOCIETY

A society is a system for facilitating interdependent social relationships according to the values, norms, and ideologies of a shared culture while, at the same time, providing sanctions against individuals who engage in what are seen as antisocial behaviors. Among the primates, humans are unique in their capacity to develop large-scale systems of interdependence by means of culturally transmitted, group-level social systems; in other primate species, cooperation is generally limited to relatives, there is little division of labor, there is little or no social cooperation to care for the sick or wounded, and there are no formal social mechanisms (let alone cultural norms) to stop dominant males and females from taking whatever they wish from weaker members of their group.

As the term is generally understood in sociology as well as in commonsense usage, a society is assumed to have three fundamental characteristics: (1) it is bounded by readily discernible territorial borders; (2) it is structurally and culturally distinctive; and (3) it possesses an objective existence that is independent of the wills or actions of individuals.

Generally (if problematically), a society’s boundaries are assumed to be those of a nation: Thus we speak of “Canadian society” versus “American society.” Moreover, the boundaries of all of a society’s institutions, including economics, kinship, and religion, as well as politics, are assumed to be roughly coterminous. A society is not hermetically sealed from others, of course; every day, thousands of Americans and Canadians cross the U.S.-Canada border, and U.S.-Canadian trade is a vital component of the economies of both countries. Still, the fact that a society is essentially a culturally mediated system for facilitating interdependence means that, in principle, such relationships are more easily undertaken within the society rather than with outsiders. At the same time, it is clear that, with the advent and gathering momentum of globalization, a global society is emerging that is characterized, in part, by the formation of mutually beneficial social structures of unprecedented scope and size, including a new international division of labor in manufacturing.

Each society is unique in the way its various components have been altered and adapted so that they can be integrated with each other. Canada’s system of parliamentary democracy is modeled after the British system; however, it has had to adapt to the existence within Canada of a large, French-speaking, and potentially separatist regional minority, centered in Quebec. In part to address the legitimate language discrimination grievances that fuel Quebec separatism, the Canadian system has moved away from the British model toward that of a constitutional democracy with enumerated rights for French speakers. Despite their internal differences, the members of a society are aware of their society’s distinctiveness and their vast store of shared experience, and this awareness informs their identity. When asked what is important or very important to their identity, many Canadians mention language, but nearly all of them stress the uniqueness of their society and their country’s unique historical experience.

Society has an objective existence that precedes the individuals who live within it, exists independent of their will and subjective perception, and constrains their thought, beliefs, and behavior. This is so because a society consists not only of one-to-one relationships, which to some extent can be negotiated and altered, but also of organizations (such as courts, schools, legislatures, and hospitals) that possess vastly greater power and resources than any individual could muster. In addition, the members of a society are affected by collective outcomes of one-to-one relationships, such as economic recessions and depressions, which again are beyond the capacity of individuals to control.

Taken together, these assumptions argue strongly for a social science that seeks social explanations for social phenomena, and these assumptions collectively define what might be termed the classical sociological perspective (c. 1880s to 1960s). At the same time, each assumption is problematic. Contemporary sociology examines these assumptions critically and asks whether they can be shown to apply empirically.

LINGUISTIC ORIGINS

The English word society has its origins in the Indo-European *sek* “to follow,” from which derives the Latin *societas*, “partnership, fellowship, association, alliance”—that is, followers of a common, mutual interest or common
ideal. In line with its Latin origins, the English word can be applied not only to collective historical formations such as “Canadian society,” but also to *de novo* associations that are deliberately created to provide mutual benefit, such as professional societies or mutual assistance societies. In popular usage, *society* is sometimes intended to refer to a leisured, cultured, wealthy, and fashionable elite (“high society”).

The word *society* can be used scientifically only with caution and critical reflection. It connotes systems of mutually beneficial relationships into which individuals, perceiving the benefits, freely engage. Whether social interdependence is indeed mutually beneficial, let alone entered into freely, is an empirical question.

**SOCIETY VERSUS COMMUNITY**

All modern societies are capable of creating large-scale structures that facilitate interdependence, such as markets and the division of labor. The resulting structure extends to communities within the society, but more importantly, it also draws into its web of interdependence people who have never met each other and never will. As traditionally defined, a community is a group, such as a neighborhood or the congregation of a synagogue, that is characterized by face-to-face interaction in the context of shared local customs and traditions. As understood in classical sociology, communities are necessarily limited both in population and geographic extent because they depend on face-to-face interaction (rather than large-scale interdependence) as a means of achieving group solidarity.

In classical sociology, the modern distinction between society and community owes much to Ferdinand Tönnies (1855–1936), who redefined two German words to capture the distinction. *Gemeinschaft* (community) and *Gesellschaft* (society). In the *Gemeinschaft*, people are held together by organic ties and communal ideology; in the *Gesellschaft*, social relations are impersonal and based on a perception of mutual interest. Tönnies believed, pessimistically, that *Gesellschaft* would obliterate the remnants of *Gemeinschaft*, to the detriment of the human social experience.

Today, most sociologists accept that communities arise, not necessarily from face-to-face interaction, but rather from shared meanings. Because they are capable of promulgating shared meanings on an unprecedented scale, new communication and media technologies (including newspapers, motion pictures, radio, television, and computer-based communications) are capable of creating communities that vastly transcend the limits of face-to-face interaction.

**SOCIETY VERSUS THE STATE**

In contemporary usage, a society’s boundaries are frequently assumed to be the same as that of the nation-state with which it is equated, a fact that testifies to the growing ability of states during the past two centuries to circumscribe the sphere of social relationships in which their subjects engage. It should be noted, however, that the concept of society is by no means synonymous with the concept of a state. A state is a political formation that is fundamentally concerned with the acquisition, use, and protection of power. In contrast, the term *society* refers to all the culturally mediated, patterned forms of social interaction, including political interaction, that create the conditions for interdependence among a society’s members.

The term *civil society* is often used to differentiate between the state and society. Classically, the term refers to a zone of public social interaction that is positioned between the state, on the one hand, and the private lives of individuals and families, on the other. It consists of a variety of public but nongovernmental institutions and organizations such as voluntary associations, clubs, youth organizations, mutual benefit societies, community organizations, coffeehouses, charities, trade unions, social movements, and media such as newspapers. In a prosperous society, it is assumed, civil society is vibrant.

One of the most crucial functions of civil society lies in its capacity to foster the *public sphere*, a zone of public social communication in which free, open, rational, and critical conversation can take place concerning the proper ends of society—and, especially, whether the state’s policies are serving those ends. For some theorists, especially Jürgen Habermas, a healthy public sphere is a vital component of democratic self-governance.

**THEORIES OF SOCIETY**

It is possible to find antecedents of the society concept in classical Greek philosophy and, especially, in the work of the Islamic social historian Ibn Khaldun (1332–1406); however, the concept of society as it was understood in classical sociology is generally traced to the mid-nineteenth-century work of Auguste Comte (1798–1857), who is also regarded as the founder of sociology, the English social philosopher Herbert Spencer (1820–1903), and especially Émile Durkheim (1858–1917).

Observing what Durkheim took to be the decline of communities held together by religion and tradition, the anonymity of an increasingly urbanized society, and the prospect of endemic conflict caused by the increasingly violent confrontation between capital and labor, he asked whether modern societies possessed a core of common sympathies that could serve the integrative function formerly provided by rural folk communities and traditional cultures. Of crucial concern to Durkheim was the increasing division of labor generated by urbanization and industrialization. To the cynics of the time, the widening gap between capital and labor presaged the collapse of social
solidarity and, ultimately, the end of European civilization; for example, Karl Marx (1818–1883) believed that the conflict between capital and labor testified to a fundamental contradiction in capitalist society that would inevitably result in revolution, peaceful or otherwise. Yet Durkheim had read Comte and Spencer, and was able to counter this view with the organic analogy, which interprets the various components of society as if they were organs in a body: Each of them contributes, in its own differentiated way, to the mutual benefit that stems from their cooperation.

From this analogy, Durkheim went on to argue that the widening division of labor in industrial society did not necessarily raise the specter of social disintegration. On the contrary, Durkheim argued, to the extent that society is understood as an interdependence-fostering structure, the widening scale and scope of industrializing societies would require a corresponding intensification of new modes of social differentiation to serve as the foundation for subsequent, mutually beneficial interdependence. In addition, Durkheim argued that, despite the apparently widening gulf between capital and labor, there still existed enough shared culture and shared identity to overcome the divisiveness seemingly inherent in the new industrial economies. The key, Durkheim argued, lies in recognizing that shared culture and shared identity are not causal factors in themselves, but rather epiphenomena that result from sustained, mutually beneficial, and socially structured interaction. For this reason, Durkheim did not doubt that industrial societies would generate cultural and moral orders capable of social integration on an unprecedented scale, and history has vindicated his prediction.

Durkheim’s understanding of society was informed by likening its constituent elements to an advanced, highly differentiated organism. Scientific and technological advances in the twentieth century made new metaphors available to sociological theorists. Drawing on the emerging fields of cybernetics and systems theory, in the 1930s American sociologist Talcott Parsons (1902–1979) depicted the interdependence of social phenomena in terms of a hierarchy of intercoupled systems and subsystems. Niklas Luhmann (1927–1998), a student of Parsons, drawing on chaos theory, depicted society as a complex, self-organizing system.

Beginning in earnest in the 1960s, sociologists revisited and often criticized or rejected the core assumptions of Durkheian sociology, often adopting new metaphors to capture their perspectives. With the rise of symbolic interactionism, ethnography, and particularly the work of Erving Goffman (1922–1982), society could be understood as a stage on which performers create and shape social reality. Drawing increasingly on resource mobilization theory, work on social movements suggested that society is like a game in which teams compete with each other, both to acquire necessary economic, social, and political resources and also to frame their activities symbolically in a winning way. As Marxist perspectives found their way into universities in the 1960s, society came to be seen as a battle between social classes with fundamentally opposed interests. Still, rational action theorists, such as James Coleman (1926–1995), depicted society as an economy in which actors develop elaborate networks as they attempt to maximize their self-interest.

Influenced by developments in semiotics and French literary criticism, some postmodern sociologists have likened society to a battle between contending texts or a discourse of signs; others have argued that capitalism has so infected our consciousness that virtually all social activities can be understood by comparing them to producers and consumers in a media-driven marketplace. The production of new analogies shows no sign of abating; for example, society has recently been compared to a restaurant menu, a theme park, a collection of machines, and a set of warring tribes.

CRITICISMS OF THE CONCEPT

Criticisms of the classical concept of society focus on its several problematic aspects, including the assumptions that societies are neatly bounded, that the interdependence fostered by social relationships is mutually beneficial, that society has an objective existence, and that meaning and affect are mere epiphenomena of social relations.

Until recently, sociologists have paid little attention to the problems created by uncritical assumptions regarding a society’s boundedness. To the extent that it is meaningful to talk about “Canadian society,” for example, it is because Canadian society constitutes a field of social interaction within which Canadians are more likely to interact with each other than with outsiders. Yet, in the context of globalization, Canadians will increasingly interact with foreigners; at the same time, it is clear that Quebec could be seen as a society within a society. For some critics, sociology’s willingness to equate societies with nations shows that the discipline has made an uncritical accommodation to nationalist ideology. New directions in sociological theory employ spatial and ecological analogies to tackle the boundedness problem; the boundaries of social interaction are seen as a matter to be determined by empirical investigation rather than facile assumption. In addition, cultural sociologists are developing new approaches for understanding the dynamics of multicultural societies.

At the core of the concept of society is an assumption that amounts to a quid pro quo: By giving up the opportunity to pursue private interest without constraint, people take part in social relations that are, in the end, mutually beneficial. Still, it is obvious that many social
relations are founded on asymmetries of power, and result in concomitantly unequal distributions of benefits. Critical sociologists argue that the quid pro quo concept masks asymmetries of power, which are, in their view, a key component of all or nearly all of society's structures and institutions.

Sociologists readily assume that society has an objective existence that can be scientifically studied, even though there is no physical object in the world that one can point to and say, “That is a society.” Within sociology, a field called symbolic interactionism begins by rejecting the concept that a society has an objective existence that determines the way individuals behave. In contrast, people are seen to act according to the meanings they ascribe to situations. These meanings are learned by engaging in social relations. Action arises as individuals interpret situations in light of the meanings they have learned. Although symbolic interactionism has been influential, most sociologists believe that societies are quite capable of placing people into situations in which an actor’s interpretation of the situation is not the sole determinant of social outcomes. People who live in African American slum communities, for example, interpret their situation in differing ways, but this fact has little effect on the overriding social toxicity of these racially isolated neighborhoods. Still, symbolic interactionism served to alert sociology to the need to take meaning and affect seriously and, in so doing, has contributed to the rise of cultural sociology, which is arguably the most important development within sociology to have taken place in a century. In classical sociology, meaning and affect were seen as the outcome of social relationships rather than their cause. Today’s cultural sociology (e.g., Alexander 2003) shares with symbolic interactionism a commitment to taking meaning and affect seriously; however, it also recognizes that some social structures are indeed independent of individual will and are unaffected by the meanings people ascribe to them. Cultural sociology views social relations as the outcome of processes in which meaning, affect, and social forces interplay in ways that must be determined empirically rather than by theoretical fiat.

SOCIOBIOLOGY
The scientific study of the social behavior of biological systems from an evolutionary perspective is known as sociobiology, a term coined by the entomologist and biologist Edward O. Wilson in 1975. Researchers from a diverse array of disciplines including biology, psychology, sociology, anthropology, and archaeology study social behavior from a sociobiological perspective. According to this perspective, the social behavior of animals, including humans, has been shaped by the process of natural selection in which any behavior that increases the ability of an individual to live to reproductive age and to successfully reproduce subsequently becomes more prevalent in future generations. Sociobiologists therefore attempt to understand how current social behavior would have provided a reproductive advantage to individuals of previous generations. To facilitate this process researchers identify problems that social beings recurrently faced over evolutionary history and then determine the behaviors that would have been adaptive to successfully deal with these problems. The term sociobiology has now largely been replaced with the term evolutionary psychology. Using this approach, researchers have found empirical support for the evolutionary origins of a number of social behaviors including mate attraction and selection, helping behaviors, and aggression.

MATE ATTRACTION AND SELECTION
One of the most influential theories of mating behavior is the parental investment theory proposed by Robert L. Trivers in 1972. Trivers postulated that in sexually repro-
ducing species the sex that invests the most in offspring will be more selective in whom they choose as mates whereas the sex that invests the least in offspring will compete more with each other for sexual access to the more selective sex. In humans, the minimal parental investment that a woman must expend on a child involves the nine months of gestation and parturition, plus a period of lactation that can last from several months to a few years. For men, the minimal parental investment can conceivably involve a single sexual encounter. Given that women are a more limited reproductive resource, competition among men to mate with women should have been stronger during evolutionary history than competition among women to mate with men. Consistent with the predictions derived from this theory, research has shown that men are more willing than women to take advantage of short-term sexual opportunities with different mates. In comparison, given the higher costs of reproduction for women, they are more selective than men in whom they choose as sexual partners and tend to desire longer-term relationships.

Parental investment theory also makes predictions regarding the traits men and women should find attractive in each other. If men tend to prefer short-term sexual opportunities to maximize their reproductive success, then they face the problem of identifying which women are fertile. Certain physical cues are associated with fertility, and it has been found that men are more attracted to women that possess these physical traits. For example, women with a waist-to-hip ratio around .70 (where the waist is 70 percent the size of the hips, producing a curvy appearance) and women with more feminine facial features (e.g., larger eyes, smaller chin) have been found to possess high amounts of estrogen and thus are relatively more fertile. Men are also more attracted to young women, perhaps because women's fertility continually declines through their adult years. By contrast, if women tend to prefer long-term relationships so that their high parental investment can be offset by investments from their mate, then they face the problem of identifying mates that have the ability to accumulate status and resources that can then be shared with themselves and their offspring. Research shows that women are attracted to men with good financial prospects, men who have social status, and men that are more ambitious. Women are also more attracted to men who are older than themselves, because older men have had more opportunity to turn their ambition into actual status and resources.

Once a relationship is formed, people face the problem of maintaining the relationship. David M. Buss (2000) has suggested that for humans jealousy was an important adaptation for maintaining relationships because people who became upset when they were in danger of losing their partner would have experienced greater reproductive success than those who did not. He also suggested that women and men should differ in the types of cues that activate their jealousy. Whereas a woman can be confident that she is in fact the mother of her children, because of internal fertilization, a man cannot be certain that he is the father. Paternity uncertainty should therefore have made men more sensitive to cues of sexual infidelity of their partners and wary of rivals that are friendly or flirtatious with their partners to ensure that their partner's children are also their own children. For ancestral women, securing the resources to raise highly dependent offspring was a challenge. The ability to raise offspring to reproductive age would be severely compromised if paternal investment were to be directed elsewhere, and therefore women should be sensitive to cues indicating emotional infidelity of their partners.

ALTRUISM AND AGGRESSION

Two behaviors that have also received much attention from sociobiologists are altruism and aggression. When presenting his theory of evolution by natural selection in 1859, Charles Darwin commented that his theory was not able to explain why individuals helped others, particularly when these altruistic behaviors limited the reproductive success of the helper. In 1964 William D. Hamilton addressed this problem with his theory of kin selection. He stated that because individuals share a portion of their genes with genetically related individuals, providing assistance to kin can therefore further one's own reproductive success. Helping behaviors should thus be observed to be directed mainly to genetically related individuals. Kin selection theory, although supported by research, could not account for why individuals were observed to provide assistance to unrelated individuals. Trivers addressed this problem in 1971 by proposing his theory of reciprocal altruism, hypothesizing that an individual will help an unrelated individual when the former expects to be the beneficiary of assistance from the latter in the near future. Indeed, help is directed to unrelated individuals with the expectation that these acts of kindness will be repaid.

Aggressive behaviors may also have evolved because of the adaptive benefits they bestowed on the aggressor. According to Mark Schaller and colleagues’ intergroup vigilance theory (2003), it was adaptive for human ancestors to develop a fear of strangers and of individuals who were diseased. One consequence of fear is that it can motivate aggressive behaviors to defend against perceived threats. The ancestors of contemporary humans lived in small groups and relied on each other for survival, and the presence of individuals from another unknown group could have aroused fear because of the possible threat of intruders to one’s survival. People who did not fear strangers from other groups may have been more vulner-
able to attack, whereas people who did fear intruders and acted to defend themselves and their group would have been more likely to survive. This tendency to respond aggressively to strangers may no longer be adaptive, however, given that humans now live in very large groups that are very diverse. Over evolutionary history people may also have developed a fear of others who were sick or diseased, given that the illness may be contracted and put one’s life at risk. Stigmatizing those who were ill and removing them from the group may have been one way to avoid illness given that early humans did not have access to modern-day medicine.

TESTING SOCIOBIOLOGICAL THEORIES

Sociobiological theories are tested in many different ways. Laboratory experiments have been used to test cause-and-effect relationships between variables by manipulating the context study participants are exposed to and then measuring participants’ responses. Survey studies that ask people to answer questions about their own personalities or about their likes and dislikes have been used a great deal to study, for example, the mate preferences of men and women all over the world. Field studies have been used to observe the natural behaviors of individuals as they interact in small or large groups. Archaeological records have been used to discover the types of tools human ancestors used to hunt game or to study the evolution of brain size. In addition, public records recording the behaviors of citizens of various countries over hundreds of years exist, and these records have been used to test sociobiological hypotheses regarding homicide (Daly and Wilson 1988) and the effects of birth order on behavior (Sulloway 1996).

Sociobiology is still considered a controversial field by many. Sociobiologists study current social behavior and then make conclusions about what life must have been like for humans living thousands of years ago. Because what happened in the distant past can never truly be known, opponents of sociobiology suggest that researching current behaviors does not provide insights on the evolutionary origins of these behaviors. Sociobiology has also been blamed for justifying negative social behaviors such as male violence against women and intergroup violence. Stated differently, suggesting that social behaviors evolved because they were adaptive implies that these behaviors are natural and acceptable. Although explaining why behaviors exist does not necessarily justify the existence of the behavior, many sociobiologists have not always made the effort to differentiate explanation from justification.

SOCIOECONOMIC STATUS

As social scientists in the twentieth century became more aware of and interested in social stratification and social class as a basis for understanding large areas of human behavior, interest grew in finding direct and useful ways of measuring socioeconomic status when conducting empirical research. Socioeconomic status had been taken into account in early American sociology, and seems to have been conceived as an indicator of social class itself. During the 1920s, the highly influential Chicago school of sociology had developed several creative research techniques in relation to the ecological theories of urban structure and process. Most of their research was carried out in the Chicago area and used a residential approach to social characteristics of the urban population of the Chicago area. This research was predicated on the assumption that physical distance was correlated with social distance, and that people from different ethnic groups and social classes live in different areas or zones of the city. By implication, a person’s social class location was at least indirectly indicated by the area of residence, or zone of the city. This approach was part of a larger ecological orientation to the study of urban communities and posited a close correspondence between the utilization of physical space and
Socioeconomic Status

the overall urban structure, with tendencies to place the social structure on a broad theoretical map of the city. Social stratification was regarded by these scholars as an ancillary aspect of social structure.

As a measure of socioeconomic status, the residential approach had severe limitations. Type of residence is an imperfect indicator of social-class position, as is residential location. Comparison across cities with different areal patterns of distribution of social and economic activities, including residential patterns, would also be difficult.

Interest on the part of social scientists in social class qua class itself grew during the economic depression of the 1930s. A social anthropologist, William Lloyd Warner (1898–1970), studied a northern East Coast community in the United States and used a reputational method applied to individuals. Warner and his research staff employed extensive observations in this small community where most adults had knowledge of the reputations of others residing in the community. These investigators relied extensively on the judgments and relative rankings of the status of community members by others in the small community. The application of the reputational method to Yankee City, the pseudonym accorded to the community, resulted in the designating of six social classes on the basis of reputational rankings of status.

The reputational approach to socioeconomic status applied by Warner has been found to have several problems. As a methodology, it is confined to quite small communities, a serious limitation during this last century of accelerated urbanization. This approach does not enable facile comparisons across communities and hence is limited in contributing to discussions of a national class structure. Also, as other social scientists studied other North American communities and found different numbers of social classes or strata in the other communities, questions were raised regarding reliability. The numbers of classes found in other studies ranged from two to as many as eleven or more, indicating serious problems in comparability. These various difficulties in using the reputational method for studying socioeconomic status pointed toward the need for measures with greater simplicity and precision that could be applied to larger communities, or the nation or a national sample, than was possible with the reputational method.

DEVELOPMENT OF MEASURES OF SOCIAL CLASS AND SOCIOECONOMIC STATUS

The first large-scale study of the stratification of an entire city was carried out by Robert S. Lynd (1892–1970) and Helen Lynd (1896–1982) during the 1920s and published in 1929. *Middletown*, the title of their resulting book, was also a pseudonym for a city of 35,000 people in Indiana. Their research method involved the detached observation techniques of social anthropology. *Middletown* was to be the first of two books on the social class structure and its consequences for the life of the citizens of this middle-sized city in Indiana.

The research by the Lynds made an important contribution to the study of socioeconomic status due to the simple, direct measures they used to indicate the social class position of the residents of the city of Middletown. To measure social class itself, the basic distinction the Lynds used was between people who work with *people* in selling and promoting consumer goods, ideas, or services, on the one hand, and people who work with *things*, often using tools in making products or performing services. The first category of occupations was referred to as the *business class*; the second broad category was designated as the *working class*. In Middletown, there were twice as many people in the working class as in the business class. The Lynds found that membership in one class in contrast to the other had large consequences in regard to many areas of life, including whom one married, opportunity for and likelihood of attending a college or university, club memberships, access to bank credit, recreational patterns, and even whether one owned an automobile and, if so, what sort of car was driven.

The Lynds found in their second study of the same city that by the middle 1930s they needed a more complex set of distinctions, and so they used six categories of people in their analysis of social class. These were reported in 1937 in *Middletown in Transition*. The observation of greater complexity in the class structure of Middletown was significant and seems to have revealed subtleties in social stratification that would influence others to follow in later research on social stratification.

Only a short time later the U.S. Bureau of the Census attempted a classification of occupations that reflects the recognition of growing complexity in the way people in the United States earn their living. The classification scheme developed by Alba Edwards (1872–1947) for the U.S. Census moved away from the Lynds’ original classification between businesspeople and workers and attempted to designate greater distinctions within categories of business owners, managers, and various categories of workers.

The classification of occupations developed by Edwards in 1943 had the following major categories:

1. Professional, technical, and kindred workers
2. Managers and administrators
3. Sales workers
4. Clerical workers
5. Craftsmen
6. Operatives
7. Laborers, except farmers
8. Farmworkers

The Edwards scale did represent an attempt at the development of a scale of occupations by a ranking method that correlates with income, education, and prestige. Later research in sociology and economics showed that these correlates existed, in a general sort of way. Nonetheless, earnings overlapped considerably across such categories as professionals and managers, with managers outearning professionals, though the latter is a higher category; also the classification of skilled craftsmen contained many who earned more than clerical and sales workers. The categories are actually quite heterogeneous and cover a large number of occupations that are not very similar within a category, as for example, laboratory technicians, nurses, and public educators who are classified with physicians and lawyers, within the highest broad category of professional, technical, and kindred workers.

Edwards had attempted to develop a classification of occupations within the existing census categories, and his effort sought to separate occupations that clustered by similarity of work, educational requirements, and income. The heterogeneity within his major categories prevented him from fully achieving his goal of a national occupational system of categories of jobs based on occupations recorded by the Bureau of Census.

During the late 1950s, August B. Hollingshead (1907–1980) and Frederick Redlich (1910–2004) conducted a major study of social class and its linkages to mental illness. They used a combination of the Edwards classification scheme combined with reported educational levels of respondents that progressed from grade school through graduate education. They also utilized a series of measures of the urban ecology of the community studied. Hollingshead and Redlich not only uncovered clear relationships between social class position and mental health status, but also contributed a measure of socioeconomic status, now sometimes referred to in handbooks on social measurement as the Hollingshead two-factor index of social position. The main features of occupational type and educational achievement were retained and the measures of residence and neighborhood used in the original project were dropped to make it a two-factor index.

The first attempt to do research on the national ranking of the prestige of particular occupations resulted in significant advances in 1947. This research was conducted on ninety occupations, with each receiving an estimate of its prestige rather than being categorized into a set of similar occupations represented as a class of one sort or another. This research on occupational prestige was carried out on a national sample by Cecil C. North (1878–1961) and Paul K. Hatt (1914–1953) through the National Opinion Research Center.

A national and representative sample of the entire adult population for the United States was interviewed. This first effort to create a scale of occupational prestige at the national level included 2,920 persons.

Each person was asked to select one of six alternative statements representing their opinion of the “general standing” of a job. The alternatives were:

1. Excellent standing
2. Good standing
3. Average standing
4. Somewhat below-average standing
5. Poor standing
6. Do not know where to place that one

A list of ninety occupations was read to each respondent, with opinions recorded. There was a low proportion of “don’t know” responses. Numerical weights were given by assigning a score of 100 for “excellent” and 20 for “poor,” and then averaging answers to develop a composite score. The highest-ranking scores ranged from 96 for U.S. Supreme Court Justice and 93 for physicians and state governors, down to a low of 34 for street sweeper and 33 for shoe shiner. In general, professional and managerial occupations ranked the highest and unskilled manual laboring occupations the lowest, with many office and sales positions, as well as more highly skilled blue-collar occupations, in the middle and lower-middle levels.

The respondents were asked the main reason they had ranked the occupations as they did, and income was the most commonly given reason, followed by service to humanity and education. None of these reasons was given by more than 18 percent of the sample, indicating no broad uniformity in bases for rankings.

This scale has become known as the North-Hatt scale. The scale was replicated in 1963 with a national sample of 651 adults and showed strong consistency in the prestige ratings of the occupations used in the original North-Hatt scale sixteen years earlier. These scales then began to be widely used in empirical research on social stratification.

It remained for the demographer-sociologist Otis D. Duncan (1921–2004) to expand the original scale with its ninety occupations to a more complete listing. By a weighting of income levels and education of people in various occupations, Duncan was able to construct a list of 425 occupations with composite rankings known as the Duncan socioeconomic index. This index was published in a larger work titled Occupations and Social Status (1961) by Albert J. Reiss (1922–2006), Otis Duncan, Paul Hatt, and Cecil North.
The question arises as to the benefits and advantages of the various measures of occupational prestige utilized in scales that attempt to measure socioeconomic status. In answer, it can be said that occupation is utilized by large sectors of the public in modern developed societies as an indicator of social position, and hence has some significant meaning in regard to general social status and class position. Second, occupation is clearly an imperfect indicator but nonetheless correlated to some degree with other dimensions of social stratification, such as educational level and income. It is probable that these three dimensions—occupational prestige, education, and estimated income—are utilized in a simplified manner by adult members of modern societies in placing individuals in day-to-day social interaction. A third advantage is that occupation, as scaled in measures of socioeconomic status, can be ascertained directly and without great difficulty. Connected to this third advantage is the inarguable degree of objectivity in the determination of occupation. A fourth advantage of scales that indicate occupational prestige is their ease in use in comparative and international research. This is in stark contrast to the familiarity required with community standards in the studies of status rankings and stratification in smaller cities and towns. Finally, the use of occupational rankings as a socioeconomic index can and has been successfully applied in research on national levels of stratification, as well as in research on smaller communities.

In summary, measures of socioeconomic status that are based on occupation are to be seen most strongly as a methodological index of social stratification with the limitations that an index entails. As will be discussed below, this is greatly preferred over the widespread tendency to utilize occupational rankings as a synonym, or single indicator, of social class. Some scholars have used the scores on socioeconomic status measures as an alternative to making a theoretical statement about their own position on the nature of social classes, with the effect of limiting the degree of investigation of the character and impact of social classes in social life.

There is another methodological limitation in the use of socioeconomic scales. They are widely used in correlation and regression analysis and treated as interval and ratio scales of measurement. These statistical applications utilize the arithmetic operations of addition, subtraction, multiplication, and even division. The assumption of equal-appearing intervals between the score values of the prestige ratings is a dubious assumption, as is that of an absolute zero point on the scale. No occupation has been scaled with zero prestige. The effect is the violation of some of the basic assumptions of parametric statistics used in the research on stratification.

The interest that social scientists have shown in measures of socioeconomic status is considerable, and scholars in the social sciences and neighboring disciplines have been willing to borrow these measurement scales and use them in correlation analysis with a range of variables in their fields. Perhaps this popularity of the concept of socioeconomic status, and its measurement, is a product of the interest in “status” and “status attainment” in American studies of social stratification. These concepts are most consonant with North American beliefs in personal achievement and recognizable social location or position in a community, and even ideals regarding democratic consensus. Status in popular imagery is contained within the reality of individual influence and control. An emphasis on status and status aspirations is linked with occupation, and features personal achievement and success rather than family heritage, the importance and accident of birth, much less the influence of aristocratic advantage or the more distant, structural, and superindividual effects of “class.” Status achievement and status “attainment” can also be analyzed with facility through the use of occupational rating scales that seem to quantify the prestige of occupations and their relative social standing.

The updating of the North-Hatt scale sixteen years later in 1963 by Robert Hodge, Paul Siegel, and Peter Rossi demonstrated longer-range similarity in patterns of prestige evaluations. This consistency—with a few notable exceptional occupations such as nuclear physicist, recognized by only around half of the sample in 1947 in contrast to 90 percent in 1963—was so strong that the expanded lists, along with the Duncan socioeconomic index, established the reliability of these measures. Overall, these studies have demonstrated that large sectors of the American public agree on the prestige ranking of occupations in the United States and that most of these rankings are similar across a large number of industrial societies of the world. The effect was that one or another scale for the measure of socioeconomic status has frequently been used in the interim in sociological and social-psychological research.

THEORIES OF SOCIAL CLASS AND THEIR IMPLICATIONS FOR SOCIOECONOMIC STATUS

As seen above, scholars who study socioeconomic status have conceived the inequality of socially stratified orders in complex societies as consisting of ranked statuses, with the ranks ordered on the basis of shared evaluations of the importance of the various positional ranks. An assumption of shared values is made in the approach. There is also an assumption of continuous gradations in socioeconomic status positions. Sharp breaks between status gradations are not envisioned, nor is there necessarily an individual consciousness of membership in the various status levels,
nor group interactions based on status levels, nor interacting groups based on prestige of position, nor demarked social classes that possess distinctive boundaries and objectively measured social characteristics.

In the mid-nineteenth century, an earlier tradition in social theory developed. This tradition emphasized the reality of social classes as the primary dimension of social stratification. These ideas have European antecedents and are seen most clearly in the scholarly writings as well as political polemics of Karl Marx (1818–1883), a social thinker of German origin. Born to a generation following Marx, another German scholar, Max Weber (1864–1920), offered strong criticism of Marx, but refined certain aspects of this overall approach, which carried a much greater emphasis on conflict, power, and social change in human social life. Since approximately the middle of the twentieth century, American sociologists such as C. Wright Mills (1916–1962) have also been developing conceptual approaches and theoretically informed research projects that analyze the role of power and conflict in social life.

This research continues to the present. To these conflict theorists, social stratification and social classes are among the most important aspects of society and social life, with enormous consequences for society as well as for the individual. This group of thinkers is likely to retain Max Weber’s emphasis on social class as economic behavior with consequences for the life chances of individuals. These life chances include the likelihood of experiencing such important matters as living out the first year of life, marrying within a social stratum, attending a college or university, and engaging in certain forms of political activities.

In summary, scholars using these approaches that analyze conflict and power in social life view social classes as real, and as having boundaries. Social classes in this view also have strong consequences for individual members. The relations between classes are an important aspect of social processes in complex societies, and the various social classes and their relations are significant components of social organization, particularly in advanced, industrial societies. Persons may or may not be conscious of membership in a class, and may be confused regarding their status, but the consequences of class are real, nonetheless. In this view, class membership under some conditions can lead to heightened consciousness and organized political activity.

From the standpoint of the conflict approach, the emphasis on socioeconomic status in stratification research has taken the political fangs away from the concept of social class. In their place, the study of socioeconomic status has created an image of individuals who compete for occupations and occupational status in open markets, and through their individualistic actions pursue higher status, with the prestige of these statuses based on shared evaluation of the social import of occupations with their allied skills and contributions to the social life of the society. In much of the earlier American research on socioeconomic status, classes are nominalistic classifications, or exist in name rather than by being distinguishable through definable boundaries. Status gradations are seen as continuous, without sharp breaks—perhaps resembling a ladder—rather than as broken into class components with consequences for action in the politics of redistribution. Research that favors the analysis of socioeconomic status as a continuous line in a status hierarchy is likely to utilize concepts from structure-functional analysis and to emphasize order and integration in the stratification structures of societies. This integration of stratified orders is likely to be viewed as permeating various institutional spheres, such as the family, religion, education, and economy, and to contribute to the stability of the social order.

In conclusion, social scientists whose research and theoretical orientation have convinced them that social classes are real social entities that involve inequality on significant social goods assert that there are severe limitations with the typical use of measures of socioeconomic status. In their view, the research that applies these latter measures of inequality does not grapple with the reality of social classes within the social structure or their consequences for the life chances of individuals. The research that utilizes measures of socioeconomic status is also likely to overlook power in social life and the possibilities for political action that are implied in the historical usage of social classes in analyzing important aspects of social organization.

**SOCIOLOGY**

Commonly accepted definitions of sociology agree that it is the scientific or systematic study of human society. The focus is on understanding and explaining, and ranges from the individual in social interaction to groups to societies and global social processes. Unique to sociology is its emphasis upon the reciprocal relationship between individuals and societies as they influence and shape each other.

Methods of discovery range from quantitative methodologies patterned after those of natural science with the goals of explanation and prediction to strategies for social reform and service to qualitative methodologies that focus on interpretation and understanding rather than prediction.

**HISTORICAL DEVELOPMENT AND THE FOUNDATION THEORIES OF SOCIOLOGY**

As a discipline, sociology arose early in the nineteenth century in response to rapid social change. Major transformations in the eighteenth and nineteenth centuries, such as rapid industrialization resulting in a large, anonymous workforce with workers spending most of their time away from families and traditions; large-scale urbanization throughout Europe and the industrializing world; and a political revolution of new ideas (individual rights and democracy), directed a spotlight on the nature of societies and social change.

The French social thinker Auguste Comte (1798–1857) first coined the term *sociology* to describe a new way of thinking about societies as systems governed by principles of organization and change. Most agree that Émile Durkheim (1858–1917), the French sociologist, made the largest contribution to the emergence of sociology as a social scientific discipline. Both empirical research—collecting and quantifying social data—and abstract conceptions of society were major elements of Durkheim’s research. Durkheim’s work had a major, early impact on the discipline, both quantitatively and qualitatively.

In the nineteenth and twentieth centuries two more of the giants in sociological thought emerged in mainstream German sociology: Max Weber (1864–1920) and Georg Simmel (1858–1918). Additionally, Karl Marx (1818–1883), while on the edge of sociology, had a major impact on German sociology and on the discipline as a whole. Marx was concerned with the oppressiveness that resulted from industrialization and the capitalist system rather than the disorder to which other social thinkers were reacting. Advocating revolution as the only means to end the inequality between the controlling bourgeoisie class and the exploited proletariat class created by the new industrialized society, Marx produced much of his work while in exile from his native Germany (Marx and Engels [1848] 1967). His writing provides a continuous strand of sociological theory, heavily influential in Europe and, at times, in the United States. The importance of Marx’s work in shaping early sociology also lies in how German sociology developed in opposition to Marxist theory (Ritzer 2000).

Weber’s concern with ideas and systems of ideas (particularly religious ideas) and their effect on a capitalist economic system—specifically with Protestantism as a belief system that encouraged its members to embrace
change—contrasts with Marx's reflection of the economy in ideas. Simmel's influence on sociology, unlike that of Marx and Weber, was through his studies of small-scale social phenomena. Focusing on forms of social interaction and types of actors who interact, his work was most influential on early sociologists at the University of Chicago.

In response to the poverty of immigrants and African Americans in the urban United States, projects of social reform and settlement house movements provided solutions. Much of this work was based in Chicago, where early social reformers and social thinkers combined to conduct field research and organize the first major sociology department at the University of Chicago. The sociology department, founded by Albion Small (who also founded the first sociology journal in the United States, the American Journal of Sociology, in 1895) dominated the discipline for fifty years. American students of sociology had easy access to Simmel's ideas, which fit with the micro, symbolic interactionist perspective, through his followers (and, in some cases, translators) Small and Robert Park.

During the early years of sociology in the United States, theoretical influences of the period were combined with empirical research and the social reform projects and service conducted in the Chicago area. Trained as a social worker, Jane Addams spoke out about the inhumane treatment of immigrants who were entering the United States at increasingly higher rates. She founded Hull House in Chicago to provide assistance to immigrant families and gathered a community of sociologists and politicians to discuss and act on urban problems. W. E. B. Du Bois, an African American sociologist at Atlanta University, studied similar social problems for the black community in the United States and wrote and spoke out against racial inequality.

SYMBOLIC INTERACTIONISM

Symbolic interactionism, the dominant perspective championed by the philosopher George Herbert Mead (1863–1931) and others influenced by Simmel at the Chicago school, was the first foundation theory in American sociology. Although the symbolic interactionist perspective emphasizes the reciprocal relationship between the individual and society, its critics complain that it overlooks the widespread effects of culture and important sociological factors such as race, class, and gender.

In the 1930s, as the influence of the Chicago school lessened, state universities throughout the midwestern United States began to incorporate sociology departments into their curriculum, with a strong focus on rural sociology. In the 1940s the emphasis in sociology shifted away from the type of descriptive research done at Chicago to sociological theory and empirical inquiry, with the rise of influence from departments at Columbia, Harvard, and other Ivy League universities. European theorists such as Durkheim and Weber were translated and (re)introduced, and their work inspired large growth in sociological theory, particularly structural functionalism, the dominant theory in American sociology until the 1960s.

STRUCTURAL FUNCTIONALISM

Another foundation theory within sociology, the structural functional paradigm provides a view of society as a complex system of parts working together to promote both solidarity and stability for society as a whole. This perspective owes much to Comte and his concern for social integration during the rapid social change of the period. While Comte advocated social reform, in Britain the social philosopher Herbert Spencer (1820–1903) rejected social reform as intervention in the natural process of the evolution of society. Applying the principle of "the survival of the fittest" to the adaptation of societies rather than of organisms, Spencer’s ideas initially gained a large following throughout England and the United States.

Functionalists, following Durkheim, emphasized the study of social order and how social reforms could provide remedies for social disorder. Social structures (relatively stable patterns of social behavior) function together to preserve society. In the United States, Talcott Parsons (1902–1979) at Harvard was the primary proponent of the structural functionalism theory that dominated American sociology until the 1960s. A student of Parsons's, Robert K. Merton (1910–2003) distinguished between manifest and latent functions of social structures, while allowing that there are also societal social dysfunctions for some. The influence of structural functionalism has declined since the 1960s with criticism for its focus on stability and static structures, its inability to deal with social change, and its failure to acknowledge how inequalities based on social class, race and ethnicity, and gender may lead to tension and conflict.

Following World War II the strong influence of sociological theory championed by Parsons and others concerned with the prestige of the discipline continued. Quantitative data methods were seen as the best way of making the discipline more professional and increasing prestige. Demography and survey research became more important with the availability of governmental funds for financing large research projects. Major advances in quantitative research eventually led to a variety of formal analyses for survey data, including multivariate statistics, path analysis, multiple regression, and complex causal models. In the late 1950s, however, traditional sociology came under attack for its preoccupation with theory and empiricism. The 1960s also brought challenges from field researchers and reformers to focus more on social problems.
SOCIAL CONFLICT THEORY
Social conflict theory is, in many ways, a reaction to the structural functionalist perspective. The social inequality pervasive in society and ignored by structural functionalists is seen as a source of conflict and change. Conflict theory examines how society is stratified along class, race and ethnicity, gender, and age categories, and how these categories are linked to the unequal distribution of resources. Patterns of social interaction are inherent with benefits for some and deprivations for others. The goal for conflict theory is to understand the conflict between the advantaged and the disadvantaged while also taking action to reduce inequality. The perspective is certainly influenced by Marx, although critics complain that it does not have a firm enough grounding in Marxism, which was well developed in European sociology but lacked support and understanding in the United States. Critics of the social conflict perspective also complain that its pursuit of political goals shows a lack of scientific objectivity—although this theory had significant influence on contemporary theories, such as feminist theory, which emphasize the importance of political goals.

Sociology since the 1960s has expanded its emphasis to focus more on questions of race and ethnicity and gender. There has also been an incorporation of professional fields such as criminology, industrial relations, and evaluation research. In the 1990s and 2000s a variety of new areas and topics achieved prominence in American sociology: economic sociology; nongovernmental organizations having to do with justice, human rights, the arts, and the environment; immigration and ethnic identities; inequality; the growth and influence of science and technology; and social capital as resources for social mobility, citizenship, and community participation.

MICROSOCIOLOGY AND MACROSOCIOLOGY
Micro and macro refer to the level of analysis or the area of theoretical concern. Microsociology is the study of group dynamics and interaction, whereas macrosociology focuses on large-scale social systems and institutional arrangements. One controversy about the level of analysis was often phrased as a discussion of whether phenomena could be reduced to individual level properties or whether, instead, phenomena must be viewed in terms of their “emergent” properties that do not coincide with simply aggregating the individual level. While some formulations still allude to this controversy, it is common for researchers to attempt linkages between the micro and macro by viewing the effects of one on the other.

Macrosociology At the macro level sociologists ask, what are the broad patterns of interaction that shape society as a whole, and how does this influence take place? The most common institutions, found in most societies and most often studied by sociologists, are the following five:

The family, which meets the needs of societal replenishment and the care and socialization of children. At the macrolevel, sociologists ask how the definition of family is changing and how that affects the larger society.

Education, which meets the need for the transmission of culture and social and job skills. Sociologists ask how the educational system varies across cultures and nations, how it both mirrors and perpetuates the inequality in society.

Religion, a third institution, which meets the need for explanations of the unknown. Sociologists are concerned with why religions take various forms and how religious activity affects society.

The economy, which organizes the distribution of goods and services and is a focus for sociology because it determines who—individuals, organizations, nations—gets what—resources and access to resources in nations and globally.

Politics (or “the polity,” or government), which is also a participant in the distribution of power as well as the maintenance of order. Sociology looks at how the world’s political systems vary, who has power and why, and whether there is a global political system.

Both within and outside the context of social institutions, sociologists explore why stratification (systems of ranking into power and prestige hierarchies) exists and how it determines individual societal outcomes. How do social class divisions (based on economic position in society) affect culture, opportunities, and social mobility? What is poverty and who are the poor? Why does inequality exist and how might it be overcome?

A current trend in sociological thought has to do with the process of globalization. Rapid changes in communication and transportation have transformed perceptions of time and space so that the world of personal experience is a global one. Sociologists ask how economic change has taken place, what is a global economy, and what are the implications of globalization? How is economic globalization connected to political development? As political boundaries change, how are cultural boundaries affected? How do local cultures conflict with an emerging global culture and what is the place of women and people of color in that relationship?

Microsociology Many different areas are investigated within microsociology from different perspectives using
different methodologies. Microsociology can be broadly conceptualized as considering issues related to self and identity, status and power, cooperation and competition, exchange, legitimation, and justice.

Fundamental to most areas within microsociology is the insight that individuals define themselves, based in large part on how others see and interact with them. Because interaction is central to the self, different identities are developed and projected. Research in the general area of identity and self includes both qualitative and quantitative investigations of topics such as role taking, role making, altercasting, identity disruptions or deflections, and self-referent behavior.

Much of microsociology is related to the general area of group dynamics. This area had early ties with psychology, which fashioned much of its approach including the acceptance and use of experiments as a research tool. Status and power have been consistently important areas of work within microsociology. One of the most important insights from this line of research is that status is relative to the group; that is, while people might possess the same characteristic from one setting to another, these characteristics might have very different salience in different settings.

Other group-dynamics research included a wide range of studies that could be characterized as examining cooperation and competition. While many of these examined dyads and interaction between one group and another, others examined social dilemmas—settings in which there is some degree of conflict between individual and group interests. Once resources and incentives are under consideration, exchange becomes central. Exchange formulations, some more akin to economics and others more akin to psychology, developed and took on a distinctly sociological focus by examining how the type of exchange affected both the behavior and emotion of the exchange participants. The allocation of different resources is studied within exchange formulations, and the resulting assessments, behavior, and feelings of fairness are the focus of justice and equity formulations. Related to assessment of justice is the degree of acceptance of particular institutional arrangements or legitimization.

Ethnomethodology, or method of the people, is a type of microsociology that focuses upon the everyday practices in which people engage. This field differs from most other microsociologies by eschewing the use of abstraction to summarize observations.

CHALLENGES TO THE SOCIOLOGICAL PARADIGM
Reacting against the dominant paradigm that seemed to take a male, Western European, heterosexual model of the actor as representative of all actors, various critiques developed within sociology. These critiques are extremely varied both in their focus and methodology, but perhaps the most well known were feminist critiques. Although there had been early sociological analysis of the subordination of women (Ward 1883), most of the feminist analyses of sex and gender coincided with what is usually called the second wave of feminism, dating from the 1960s. During this period there was also increased attention to race and ethnicity.

Many of the sociological feminist writings emphasized the subordination of women and the institutionalization of patriarchy. Some of this work questioned the sex and gender association and sexual categorizations as well. One branch of this developed into “queer theory,” a critique of heterosexual assumptions and power.

For the most part, feminist and other critical approaches did not question the fundamental approaches to the study of sociological phenomena. Rather, the feminist literature emphasized substantive issues that centered on societal power differentials that lead to a wide variety of life experiences that constrain almost every aspect of women’s lives. Another literature emphasized how “taken for granted” assumptions of gender and sex affected what observers saw and how they interpreted it. However, there was another group of feminists who challenged traditional epistemologies and argued that who the observer was determined what could be known. This is a radical claim because it violates a traditionally accepted tenet of most sciences that intersubjectivity can be obtained: that different people can be taught to see what others can see.

Postmodernism Sometimes closely aligned with feminist critiques are postmodern critiques. These critiques emerged in the late 1970s and into the 1980s. Postmodernism is a set of sensitizing concepts and ideas rather than a well-developed and agreed-upon set of premises. These concepts challenge traditional views associated with the Enlightenment. In particular, the concepts of objectivity, the transparency of language, and the separation between science and politics are questioned. Postmodern critique has been important across most of the social sciences and the humanities, alerting sociologists to how the political becomes enmeshed in the way questions are asked and subsequently answered. Along with this is attention to grand “narratives,” or ways of telling particular types of stories. From this perspective, science is one type of narrative and does not necessarily have a status different from other types of narratives such as folklore. The emphasis is upon how scientists come to believe what they believe. Some particularly radical versions of postmodernism suggest that empirical reality has little effect upon the development and testing of theories.
THE ROLE OF SOCIOLOGISTS
There is a continuing debate within sociology about the proper role of sociologists. This debate echoes questions that have always been associated with sociology: Are sociologists scientists? Are sociologists advocates and reformers? Are sociologists scholars who practice a social science, whose methodology differs from that of the natural sciences?

Because sociologists vary in their orientation, their perceived and expressed views also vary. There are some who steadfastly claim that sociologists should not become involved in political agendas or arguments lest they jeopardize their dedication and reputation for being oriented toward the truth rather than toward advocacy. There are others who argue that the subject matter of sociology dictates that sociologists become involved in providing information that reflects upon different policy initiatives. This approach separates advocacy for a particular position from provision of information. Still others argue that sociologists should be advocates for particular policies, given sociological evidence. An example of such advocacy was the American Sociological Association’s filing of a brief to the U.S. Supreme Court on behalf of the University of Michigan Law School and the Student Intervenors in Grutter v. Bollinger (2003). In this case, the Association argued that sociological research clearly and consistently documented the pervasiveness of race in life experience such that universities cannot adequately assess candidates or their potential without considering it.

Decisions about the role of sociologists are frequently contested among sociologists themselves—a clear indication that perspectives, methods, and approaches vary considerably. However, because these contestations are often in public sociological forums, it is also a demonstration of the tolerance, or at least acceptance, of the variability within the discipline.

SOCIOLGY, AFRICAN
The defining basis of African sociology is that it takes African ontological standpoints as its point of departure, not just the description or analysis of the African conditions. As the systematic study of sociational life and dynamics, sociology can neither be restricted to the study of societies created in the wake of the Industrial Revolution nor accommodate the Enlightenment’s spatial division of labor between sociology and anthropology—with the latter as the study of nonindustrial societies. Similarly sociological analysis predates nineteenth-century Europe.

AFRICAN SOCIOLOGY IN ANTQUITY
’Adb al-Rahmān Ibn Khaldūn’s three-volume Kitāb Al-‘Ibar is a major sociology work on African antiquity (Dhaouadi 1990, Alatas 2006). In the first volume, Muqaddimah (1967 [1378]), Ibn Khaldūn set out the framework for adjudicating between competing data sources; the volume was self-consciously sociological. He outlined his new “sciences” of human organization and society 452 years before the first volume of Auguste Comte’s six-volume The Course of Positive Philosophy (1830) was published. Ibn Khaldūn also discussed the concept of asabiyyah (group feeling), or the normative basis of group cohesion, how it decomposes and is reconstructed, and the ways it manifests at different levels of social organization and among different groups. This was 515 years before Émile Durkheim’s The Division of Labour in Society (1893) was published.

TWENTIETH-CENTURY AFRICAN SOCIOLOGY
In contemporary Africa, sociology is perhaps the social science discipline that has benefited most from the “nationalist” project, both as a state-building project and as an intellectual endeavor. Sociology benefited from the state-building project as the number of universities and student enrollment grew exponentially. As an intellectual project, sociology flourished in the wake of the rebellion
against anthropology and its “epistemology of alterity” (Mafeje 1997). In a series of articles published between 1967 and 1971, Bernard Magubane (1971, 2000) led the charge against social anthropology and its alter ego Sociology in Africa. Magubane’s works involved the articulation of African ontological standpoints in the face of Eurocentric discourses of “othering.” While most of the early academic African sociologists were trained as anthropologists, Omafume Onoge’s rejection of the feasibility of being “a native anthropologist” (Onoge 1977) reflected a wider revolt. African sociology, he argued, must break with the alterity and negation endemic in “applied anthropology.” Archie Mafeje’s “The Ideology of Tribalism” (1971) was a partial and situational rejection of the concept of “tribe” and a substantive rejection of “tribalism” as a viable concept for explaining political relationship in Africa. The paper was part of a wider rebellion against alterity.

In many ways Aimilcar Cabral prefigured the concerns expressed by Magubane and others. Cabral’s “Brief Analysis of the Social Structure in Guinea” (1964) 1970 and “The Weapon of Theory” (1966) 1979 are exemplary sociological analyses and products of field methods. The former served as the source codes for “The Weapon of Theory,” which set an important departure from the dominant Marxist discourse of the time; it derived from a specific African ontological standpoint. If for Karl Marx and Friedrich Engels the history of humankind is the history of class struggle, Cabral argued that “the true motive force of history is the mode of production.” The mantra of class struggle not only runs against the grain of observed historical patterns, it produces “for some human groups in our countries … the sad position of being people without history … [and negates] the inalienable right of every people to have its own history” (Cabral 1979, p. 125).

FROM REVOLT TO AFFIRMATION

Beyond revolt, sociology also involved the affirmation of African ontological standpoints. N. A. Fadipe ([1939]1970), Cabral, Magubane, and Mafeje reflect such affirmation. Here Mafeje’s The Theory and Ethnography of African Social Formations (1991) signaled an epistemic shift. The concept of “tributary modes of production,” originally developed by Samir Amin (Mafeje 1991, p. iv), was the organizing framework for Mafeje’s study of the interlacustrine kingdoms of the Great Lake region. The idea of “tributary modes of production” was meant to capture what was “outside the purview of European history” and needed to “be understood in their own terms” (Mafeje 1991, p. iii). What Mafeje produced was a concept of tributary relations that transcended several dimensions of the contents that Amin gave it.

Ruth First’s The Barrel of a Gun (1972 [1970]) was an important development in political sociology; it was such a nuanced deployment of the category of class in explaining coup d’état on the continent that it fundamentally altered the debate. This was against the dominant Africanist explanation that gave primacy to ethnicity or “tribalism.” Peter Ekeh’s “Colonialism and the Two Publics in Africa” (1975) represented a similarly important deployment of grounded scholarship and a sociological mind-set in making sense of contrasting behaviors of the “political elite” in the realm of the state, on the one hand, and the “primordial public” of familial domain, on the other. In spite of the sociological contents of Ekeh’s analysis, it has taken an essentialist form in the hands of several Africanists.

A major development in African sociology since 1980 is the effort to use endogenous ontological narratives as source codes for sociology. A major strand was pioneered by Akínsólá Akiwōwọ; another was inspired by what Oyèrónké Öyewùmí called the African “world-sense” (Öyewùmí 1997, p. 3). Akiwōwọ’s works (1983, 1986, 1988a, 1988b, 1999) involved distilling sociological concepts from the Ọfá literary corpus (a system of life commentaries, discourses, and divination among the Yoruba). Jimi O. Adésìnà (2002, 2006) extended the insights from Akiwōwọ’s works, arguing that Ọfá texts and the wider Yoruba ontological narratives offer distinct epistemic insights: Tbí-Tibre logic, the “mutual self-embeddedness of seemingly contradictory things” (Adésìnà 2006, p.13). The implications for sociology are conceptual and methodological. These involve a sociological orientation to sociational life that embraces the coexistence of “opposites” and the open-endedness of outcome in social interaction or between contending social forces, nuanced discourse, and embracing senses, reason, and inspiration in sociological research.

In the early twenty-first century the most exciting area of sociological work is in the field of African gender scholarship. Much of these derive works from using African “world-sense” in sociological inquiry. The works of Ibi Amadiume (1987) and Öyewùmí (1997, 2003, 2005) represent distinct sociological insights and allow for epistemic ruptures from the dominant North American and European feminist scholarship. As Öyewùmí noted, “Gender categories are [not] universal or timeless … [or] present in every society at all times” (Oyewùmí 1997, p. xi). The inscription of gender ordering in the anatomical body or the coincidence of anatomical maleness and anatomical femaleness does not reflect the experience historically or even contemporarily in the two contexts in which they worked. Igbo and Yoruba languages are gender neutral, and their social structures privilege age seniority over gender difference. Seniority within a consanguine relationship is the primary marker of social position.
Amadiume and Oyéwùmí demonstrated across the spectrum of social, occupational, political, and economic ordering in both contexts that “biology [did not and does not] determine social position” (Oyéwùmí 1997, p. 17). Both have inspired other African scholars to explore other cultural contexts. Beyond scholarship, these works are valuable for women’s rights struggles. Much of the androcentric power plays and diminution of women that is often claimed in the name of “tradition” is not traditional.

SOCIOLGY, AMERICAN

American sociology is generally viewed through the prism of accomplishments made by native-born white males at predominately white institutions in theory, methodology, and various substantive areas of research. The history of American sociology often begins by noting that William Graham Sumner (1840–1910), during the 1872 to 1873 academic year, taught the first sociology course in this nation, Principles of Sociology (Bernard 1948). Further investigation into the history of the discipline highlights Arthur B. Woodford, who, in 1885 at Indiana University, became the first faculty member in the United States to have the word sociology in his official title (Himes 1949). While the first named department of sociology was established at the University of Kansas in 1889, it is generally accepted that American sociology began in earnest upon
the emergence of the Chicago school of sociology, the moniker bestowed on scholars led by Robert Park (1864–1944) and Ernest W. Burgess (1886–1966), who were engaged in sociological activity at the University of Chicago between 1915 and 1930. Parallel with the origin of the sociology department at the University of Chicago in 1892 was the strengthening of the social gospel movement in the United States. The social gospel movement placed the salvation and uplift of American society above the salvation of one’s individual soul. While proponents of the social gospel were interested in ameliorating urban problems, early American sociologists were interested in studying the demographic transition from rural to urban society through scientific inquiry and practical sociology, as practiced at Hull House in Chicago by Jane Addams (1860–1935) and by the antilynching activity of Ida B. Wells-Barnett (1862–1931). It was a common interest in issues such as the expanding urban population that led a group of like-minded sociologists to organize their own professional association.

The American Sociological Society (now called the American Sociological Association) was established in 1905 with Lester F. Ward (1841–1913) as its first president. Seeking to separate itself from closely related disciplines, men such as E. A. Ross, Albion Small (1854–1926), and C. W. A. Veditz (1872–1926) spearheaded the founding of this organization. While the accomplishments of early Chicago sociologists such as Park and Burgess and notable early American sociologists such as Ward, Small, Sumner, Ross, and Franklin H. Giddins are laudable as they helped define this emerging field during its infancy in the United States, few are aware that there existed during this era a parallel world of unacknowledged sociologists whose contributions to the discipline were equally, if not more, significant than those traditionally revered as the fathers of the American brand of sociology.

The teaching of sociology at black institutions began in 1894 at Morgan State University. It is provident that the emergence of this discipline in America coincided with the birth of black colleges that, in many respects, were borne from black Americans’ attempts to improve their condition in this nation. According to L. L. Bernard, “Sociology [in America] was first accepted by the smaller institutions of the South and by the Negro colleges. The reasons for the Negro interest is, I think, sufficiently evident in the fact that a minority group was trying honestly to understand the social situation in which it found itself” (1948, p. 14). Ultimately, black American scholars viewed sociology as a tool with which to challenge their second-class citizenship through the establishment of research programs designed to formulate strategies to ameliorate the social, economic, and physical conditions uncovered through objective scientific research. Foremost among the institutions that established research programs on the “Negro problem” were Tuskegee University, Howard University, Fisk University, and Atlanta University.

Tuskegee University established the Department of Records and Research, under the direction of Monroe N. Work between 1904 and 1945, for the purpose of conducting research on black Americans. Foremost among Work’s accomplishments as the director of this program was the publication of the Negro Yearbook. This pamphlet periodically detailed the horrific and gruesome practice of lynching and other forms of violence against black Americans and was instrumental in the eventual demise of the barbaric practice. At Howard University, where Kelly Miller (1863–1939) taught the institution’s first sociology course in 1895, the leadership of E. Franklin Frazier (1894–1964) during the 1930s was the driving force behind the “Howard school of thought.” This concept refers to the school’s “transitional [theory] that broke away from the dominant biological/genetic [racial theory] paradigm” (Henry 1995, p. 49) that was instrumental in introducing a multicultural perspective on race relations. Inquiry into the substantive area of race was also undertaken at Fisk University during the United States’s Jim Crow era. Under the direction of Charles S. Johnson (1893–1956), the Race Relations Department was established to develop effective strategies by which relations between blacks and whites could be strengthened. It was at the annual institutes held at Fisk that, for one of the first times in the South, black and white Americans were able to intelligibly discuss the “Negro problem” in a safe environment, where action plans directed at bettering relations between blacks and whites were developed and implemented. While the research programs established at Tuskegee, Howard, and Fisk deserve increased attention from contemporary sociologists analyzing significant contributions to the discipline by early American sociologists, to a growing number of scholars Atlanta University stands alone as the most significant and important research center, regardless of race, during the early years of American sociology. In 1895 Atlanta University initiated a program of research, directed by W. E. B. Du Bois between 1897 and 1914, into the social, economic, and physical condition of black Americans. According to Earl Wright II (2002), the Atlanta Sociological Laboratory, the name bestowed on the group of scholars engaged in sociological activity at Atlanta University between 1895 and 1924, rightfully deserves the distinction of the first American school of sociology and birthplace of urban sociological inquiry, given that the establishment of the Atlanta school and its institutionalized program of urban sociological inquiry predates the Chicago school by almost twenty years.

In addition to serving as a resource in the struggle for human rights in the United States, black colleges were often the destination, and salvation, for many Jewish scholars forced into exile upon Adolf Hitler’s ascension to power in Germany in the early 1930s. Scapegoated for
Germany’s problems, Jewish sociologists such as Ernst Borinski (Tougaloo College), John Herz (Howard University), Viktor Lowenfeld (Hampton Institute), Ernst Manasse (North Carolina Central University), Fritz Pappenheim (Talladega College), and Donald Rasmussen (Talladega College) obtained positions at black colleges where their experience as minorities was an educational asset in their professional and personal interactions with black college students, faculty, and the community (Cunnigen 2003).

The history of sociology has traditionally minimized the contributions of people of color, women, gays and lesbians, and other minorities. Consequently, it is of manifest importance that contemporary and future sociologists utilize alternative theoretical frames to support the recognition and canonization of marginalized scholars. Repudiation and revision of the traditional means of canonizing sociologists will result in the overdue and deserved recognition of the contributions of scholars who, by virtue of their race, sex or gender, or sexual preference, existed as “outsiders within” their own profession.

SOCIOLOGY, ECONOMIC
Economic sociology (ES) forms a specific sociological subfield. As with sociology—its genus— itself a multiparadigm discipline, there is some disagreement about what exactly falls under ES’s rubric. To counter this difficulty ES has been defined broadly as “the sociological perspective applied to economic phenomena” (Smelser and Swedberg 2005, p. 3).

While both ES and economics study the economy in its multiple expressions, they are at variance with each other. At the risk of oversimplification, the starting point for economics is the isolated rational economic actor; whereas for ES, actors always operate in social, thus relational, contexts and do so reflexively.

EARLIER PERSPECTIVES
The sociological look upon economic phenomena has marked sociology from its outset, so it is meaningful to distinguish ES into old and new segments. Old ES refers largely to the relevant parts in the work of sociology’s founding fathers, for example, Karl Marx, Émile Durkheim, Max Weber, and Georg Simmel. Indeed, Marx was concerned with the social designation of the commodity and with commodity fetishism. He also analyzed capitalism’s origins as well as capital as a social relation. Durkheim was directly interested in this field, which he—along with Weber—named as such. He was particularly concerned with the development of the division of labor while he criticized economists for their tendency to construct an exclusive economic world, which was arbitrary and one-sided because the social dimensions were excluded or neglected, whereas he linked anomie to modern economic activity. For his part, Weber delved at length in the sociological study of economic institutions and of processes pointing out that economic action is a special form of social action. Weber advocated considering both the meaning with which actors imbue their economic action (e.g., in his Protestant Ethic and the Spirit of Capitalism [1904–1905]) as well as the social dimension of economic phenomena. By contrast Simmel’s work is not systematically concerned with ES and is only dotted with references of an ES concern, such as analyses of interest, competition, and interlinkages between money and modernity.

Sociological interest in the economy subsided during the 1920s, although authors such as Joseph A. Schumpeter, Talcott Parsons, Neil Smelser, and Karl Polanyi offered contributions to the discussion. Since the 1960s, the attempts of some economists to extend economic interpretations into social phenomena—an approach called economic imperialism—challenged the established division of labor between economics and sociology. This provoked sociologists’ response, which culminated in the reemergence of ES. The wider frames of the new ES, as Jens Beckert (1996) pointed out, are delineated by two parameters: It aims towards a sociological understanding of economic processes and structures, and critiques established economic types of analysis. In the meantime, increasingly, mainstream economics has come to accept a role for the social dimension, although conceptualized quite differently than it is in ES.
CONTEMPORARY PERSPECTIVES

Mark Granovetter first discussed the new ES in “Economic Action and Social Structure” (1985). Granovetter, a key figure in ES, has pointed out that all economic action and phenomena are embedded in concrete networks of social relations, social structures, normative arrangements, and institutions that constrain and channel them in particular ways. Unlike the view of Karl Polanyi, for Granovetter these actions and phenomena are more thoroughly embedded in modern societies than in premodern ones. The concept of social embeddedness, which is identified with ES, despite some attempts to define it narrowly, remains a general concept.

Granovetter’s own work on how people obtain a job at the local level was an early application of the social embeddedness idea. He argues that getting a job, or accessing the labor market, is intrinsically a social process linked to the job seeker's social ties in specific social milieus, which are formulated and distributed under the overdetermining impact of social class. This thesis, known as the strength-of-weak-ties thesis, has found corroboration in a wide range of social contexts in the United States and elsewhere, for instance in Greece and Russia. Recent U.S. research with respect to other social divisions, such as gender, race, and ethnicity, on matters pertaining to employment and work have identified the prevalence of continuities in the transmittance of social inequalities rather than of discontinuities, which highlights the multifaceted social dimension in labor markets.

Another key concept in ES is that of the social construction of economic phenomena, which draws from the theory of constructivism advanced by Peter Berger and Thomas Luckmann in 1966. Social construction refers to the fact that economic arrangements, institutions, and regulations do not have an a priori independent existence. Instead, they are formulated as a result of human social interaction and purposeful intervention that take place in a specific social context. Once, however, an economic structure comes into being it may assume an objectivity that constrains and impacts upon economic action and practices.

Thematically, research in ES has expanded to include analyses at the micro-, mezzo-, and macro-levels of firms, markets, consumption, entrepreneurship, business groups, money, migration, networks, trust, development, formal/informal work, varieties of capitalism, forms of capital, other economic institutions, the role of culture, and other areas, with most interesting results. Such research has contributed to the deciphering of aspects of the economy, and some of the most attractive examples of ES’s fruiton are to be found in the work of, among others, Viviana Zelizer on the shifting meaning of money (1994), Richard Swedberg on Weber’s ES (1998), and Neil Fligstein on contemporary market societies (2001).

While the expansion of empirical research continues, ES’s theoretical production is currently not keeping up with expectations and needs to advance. Accordingly, researchers such as Swedberg suggest that elaborations on the sociological concept of interest and on an interest-based concept of institutions may provide new vistas for ES.

European Sociology

European sociological thought can be traced to three major sources: the Enlightenment, or Age of Reason, of the eighteenth century; the Industrial Revolution; and the romantic period's counterreaction to these ideological, social, and political changes. Although there are important prefigurations of sociology (for example in the thought of Montesquieu, Marquis de Condorcet, Adam Smith, and others), the roots of modern sociology lie in the work of Auguste Comte (1798–1857), who coined the term sociology, Karl Marx (1818–1883), Émile Durkheim (1858–1917), and Max Weber (1864–1920). The last three are conventionally represented as the founding fathers of the discipline.

The great question posed by these thinkers is that of understanding the history and consequences of the seismic changes associated with the origins of modern capitalism (Marx and Weber), industrialization and individualization (Comte and Durkheim), and the new social order of modernity (Weber). For Marx the central focus is upon the global effects of the capitalist mode of production with its new classes and class conflict, the alienating impact of new forms of factory production, and the rise of the working class movement. For Weber, the concern shifts to understanding the ethical and religious roots of rational conduct and institutions in Europe and North America, comparative analysis of earlier European social structures and non-European civilizations, and characteristic features of modern society (the modern state and rational administration, modern capitalism, democratic politics, bureaucracy, and so on). With Durkheim the central problem is the changing basis of social solidarity (from mechanical to organic solidarity) and the corrosive impact of individualism upon traditional social orders.

Sociology adopted two related perspectives, one focusing upon the structure and dialectics of social relations (the European paradigm) and the other emphasizing the evolution of whole societies along social Darwinian principles. The latter is best represented by early American sociology, especially in the writings of William Graham Sumner (1840–1910), Lester Frank Ward (1841–1913), and Franklin H. Giddings (1855–1931). The guiding source is not Marx or Durkheim but the English evolutionary and individualistic thinker Herbert Spencer (1820–1903). Evolutionism informed by individualism and native pragmatism provided the framework for speculations about social organization, institutional adaptation, and change. However, the European tradition was not totally ignored. It entered into the texture of American sociology through the work of Albion Woodbury Small (1854–1926), the founder of the first American department of sociology at the University of Chicago in 1892 and influential editor of the American Journal of Sociology (from 1895). Through Small's teaching American students gained access to the conflict tradition of Georg Simmel (1858–1918). Small also helped shape the Chicago School of W. I. Thomas (1863–1947), Robert Ezra Park (1864–1944), and Ernest Burgess (1886–1966). This is the context in which American sociology discovered its unique philosophical voice in the symbolic interactionist philosophy of George Herbert Mead (1863–1931).
After Durkheim's death, Marcel Mauss (1872–1950) and Maurice Halbwachs (1877–1945) continued his legacy. This would prove decisive in shaping the structural anthropology of Claude Lévi-Strauss. In Germany, Marxism regressed to a dogmatic evolutionism in the form of Second International Marxism (best represented by the Soviet theorist Nikolai Bukharin [1888–1938]) but was reinvigorated by the Frankfurt School (Theodor Adorno [1903–1969], Walter Benjamin [1892–1940], Max Horkheimer [1895–1973], and others). Weber's legacy was more diffuse, transformed into the traditions of conflict theory (later represented by such thinkers as Lewis Coser [1913–], Ralf Dahrendorf [1929–], and John Rex [1925–]), action theory, phenomenological thought (through Alfred Schutz [1932–1998]), and figurational sociology (Norbert Elias [1897–1990]).

Post–World War II sociology marks a decisive shift to the American context both in the volume and quality of empirical research (associated with the Chicago School of ethnography, the Columbia School of Robert Merton [1910–2003], Paul Lazarsfeld [1901–1976], Samuel Stouffer [1900–1960], and others) and the emergence of the most original synthesis of European action theory in the work of Talcott Parsons (1902–1979). Parsons’s model of social action theory in *The Structure of Social Action* (1937) was later elaborated into a rather rigid form of structural functionalism and toward the end of his life into a general systems model of societal evolution. American empiricism and Parsonian sociology are often described as the orthodox consensus of post–World War II sociology.

The breakdown of the functionalist consensus came in myriad forms: rejection of Parsonian conservatism (C. Wright Mills [1916–1962] and Alvin Gouldner [1920–1980]), the behaviorist alternative formulated by George Homans (1910–1989), the exchange theory of Peter Blau (1918–2002), symbolic interactionism (represented by Herbert Blumer [1900–1987] and Erving Goffman [1922–1982]), phenomenological and interpretive sociology (Alfred Schutz [1899–1959], Aaron Cicourel [1928–], and Harold Garfinkel [1917–]), and the resurgence of interest in conflict sociology (Randall Collins [1941–]), European critical theory, and reflexive sociology (Alvin Gouldner, Alan Blum, Peter McHugh, and others). This is the period of the *theory wars* characterizing the late 1960s and 1970s. The result was the demise of structural functionalism as the sole framework for sociological thought and research and the emergence of alternative perspectives from within the European tradition. The most prominent of these are the *structure* theories of Anthony Giddens (1938–) and Pierre Bourdieu (1930–2002) (essentially trying to overcome the separation of *action* and *structure* in sociological explanation), the reformulation of critical theory as a paradigm of communicative action (in the work of Jürgen Habermas [1929–]), the globalization and world-system perspective associated with Immanuel Wallerstein (1930–) and Manuel Castells (1942–), the revival of reflexive sociology (for example in reflexive approaches to science, ethnomethodology, and reflexive modernization theory), and the appearance of postmodern and poststructuralist discourses (associated with the names of Michel Foucault [1926–1984], Jean Baudrillard [1929–], Jean-François Lyotard [1924–1998], and Jacques Derrida [1930–2004]). In the twenty-first century ideological differences between European and American social thought are less entrenched, and the future promises new dialogues with the classical thinkers and new forms of thinking in response to the postmodernization of the global economy.

SOCIOLOGY, FEMINIST

Sociology can be understood as a field that focuses on the interaction of individuals within society, examining the diversity of men's and women's lives and the fundamental structures of power, inequality, and opportunity that shape their experiences. Numerous feminist theories have entered sociological discourse through textbooks, scholarly articles, and at conferences. However, as Judith Stacey and Barrie Thorne (1985) conclude in their far-reaching critique of the discipline, sociology, unlike history and anthropology, has not undergone the conceptual transformation necessary for a feminist revolution. Similarly, Joan Acker’s 1989 article argues that the extensive knowledge and critiques of recent feminist scholarship “neither have been integrated into, nor have they transformed the old, ‘general’ theories of society” (Acker 1989, p. 65). Although feminist work challenges theories based on a normative male subject, mainstream sociological research
Feminist studies, which seeks to interpret women's position and identity in society, is inherently fused with sociological questions surrounding social structure, culture, and economic stratification. Feminist scholars within sociology, like their counterparts in other disciplines, have asked how gender is constructed, how it is organized in social institutions, and how social change is possible. It has been argued that gender differences are not natural or biological but learned from infancy. Gender differences are maintained by key social institutions such as education, marriage, popular culture, news media, religion, government, and law. The concept of patriarchy, the systematic organization of male supremacy, is one that many feminist theorists find useful. This concept does not refer simply to a collection of individuals but a system whose core value is control and domination. Everyone is involved and implicated in this system, but each can choose how he or she participates. This emphasis on a wider system is crucial. Without it, one's thinking and discussion are reduced to the personal level, resulting in accusations, defensiveness, and hurt feelings.

Sociology's own male bias and Western foundation structures academic scholarship and theory within a male interpretation. From its inception, the discipline was conceptualized and articulated by men with interpretations of social issues and phenomenon grounded in their own experiential backgrounds. The epistemological issues that feminist researchers address when applying research methodologies are rooted in ideas and methods influenced by male hegemony over academic and scientific discourse. These issues encompass, but are not limited to, examinations of the multiple dimensions and processes that generate women's social standing, as undertaken by Niara Sudarkasa (1973), Rae Blumberg (1984), and Susan Tiano (1987). Such examinations allow for the understanding that women may have autonomy but little power, economic resources but limited autonomy, or power as members of kin groups but no access to economic resources independent of kin ties. Without an awareness of such multidimensionality in classic stratification models, inequalities seem reducible to natural differences between men and women.

Much of the work of liberal, socialist Marxist, and radical feminist theories and some of the paradigms developed, such as the woman as other, woman as victim, woman as private property, and woman for exchange are consistently found in sociological works. Gender inequalities play a significant role in the triangle of sociological stratification—race, class, and gender—in addition to the stratification among feminist theorists themselves. For example, debates within the women's movement have highlighted some of the original notions of feminism as supporting a white, middle-class ideology that negated women of color and those with lower economic positions. The effect of this stratification among feminist theorists themselves has had an impact on feminist sociology's role in the twenty-first century, rendering it difficult to address feminist issues for women all over the world and bringing forth the field's own Western female bias.

The feminist movement, from its inception, has often been critiqued by African American women and other nonwhite women, such as Willa Hemmons (1980), Vivian Gordon (1987), and Rebecca Walker (1995), as being racist and exclusive. “Contemporary feminist theory, however,” as Delores P. Aldridge notes, “attempts to embrace multiculturalism, which mandates curricular attention to the experiences, historical and contemporary, of women and men of color, lesbians and gay men of all racial and ethnic groups, and women with diverse sexual, racial, and ethnic identities” (2005, p. 405). Nonetheless, feminist theory continues to face challenges as it attempts to explain the realities of these various groups of color. Many nonwhite women are calling for new theories with new names such as Africana womanist theory, Latina feminist theory, and Chicana feminist theory.

Sociology, Institutional Analysis In

Institutional analysis addresses the processes by which social structures—including both normative and behavioral elements—are established, become stable, and undergo change over time. It addresses the fundamental issues of social order and shared meaning. The normative elements include schemas, values, norms, and rules; the behavioral elements include activities, routines, interactions, and the use of resources. More so than the other social sciences, sociology has from its origins to the present time steadfastly placed the examination of institutional structures and processes at the center of its scholarly agenda.

Although attention from sociologists has been steady, the ways in which institutions are viewed and explained have varied substantially among scholars and over time. Leading classical European scholars reflect, and were no doubt partly responsible for, this diversity. Karl Marx argued that materialist structures gave rise to ideologies justifying their legitimacy—in effect, that behavioral systems determined normative frameworks. By contrast, both Max Weber and Émile Durkheim insisted that normative (symbolic) elements played an independent role in the structuring of social orders. Durkheim, particularly in his later work, stressed the important role that shared cognitive frames and belief systems—“collective representations”—played in the stability and meaning of social life. And Weber stressed the importance of “interpretation”—the employment of shared meanings by the social actor that mediate between the actor and the materialist conditions confronted.

Scholars such as Herbert Spencer and William Graham Sumner treated institutions as providing the specialized “organs” of societies, performing distinctive functions. The rules and relations defining appropriate behavior were observed to vary across political, economic, religious, and kinship sectors, and thus to give rise to diverse institutional complexes. This vision of functionally specialized subsystems organized around distinctive norms and values provided the basis for much of the research agenda for sociologists throughout the twentieth century, culminating in the theoretical codification of Talcott Parsons (1951), with his view of societal sectors differentiated by distinctive “pattern variables” (value dichotomies, such as universalism/particularism and ascription/achievement). While most sociologists pursued this macro-orientation, a few, such as Charles Horton Cooley and George Herbert Mead, emphasized the micro-foundations of institutions, arguing that it is in the minds of individuals that connections between symbols and actions take place.

In the latter part of the twentieth century, two developments have been of special significance. First, the insights of Cooley and Mead were revived and reformulated by phenomenological scholars, especially Alfred Schutz and Peter Berger and Thomas Luckmann (1967). They stress the extent to which (1) social reality is a social construction; and (2) the relative importance of shared cognitive conceptions (ideas, schema) rather than normative commitments (emphasized by Parsons among others) in the establishment and preservation of social order. Meyer and Rowan (1977) applied these ideas to help account for the similarities observed in the structures of both nation-states and formal organizations. The second important development is the theoretical work of Anthony Giddens (1984), who asserts the value of privileging social processes over social structure—“structuration” versus structure. He emphasizes the “duality” of social structure, which operates both as social context—providing the framework within which all social action takes place—and as social outcome: a product that incorporates earlier understandings and practices, but also modifications introduced by present users.

DiMaggio and Powell (1983) applied these insights to analyze the structuration of organizational fields—collections of dissimilar organizations engaged in interrelated activities in some specialized social arena (e.g., automobile production or delivery of mental health services). DiMaggio (1991) first examined the often contentious processes by which such fields come into existence, select appropriate logics and forms, and begin to operate as a taken-for-granted part of the social world. These twin emphases on cognitive systems influencing structuration processes have been pursued productively in the past two decades by scholars examining the emergence and dominance of organizations as actors in modern societal structures and their coevolution within specialized organizational fields (Scott 2001).

SEE ALSO Social Structure, State, The
The nature of knowledge has been a central problem of philosophy at least since Greco-Roman times. Plato (427–347 BCE), for example, in *Theætetus* adopted a scientific approach to knowledge and cognition. Centuries later, the philosophers of the French and Scottish Enlightenment recognized that all social differences had social origins and were thus the result of factors subject to human control.

In general, however, philosophers have attempted rather to demonstrate that a sociology of knowledge is neither possible nor desirable. Immanuel Kant (1724–1804) thus argued that while there cannot be perception without conception, the constitutive components of cognition are a priori. Similarly, empiricists of various persuasions have maintained that scientific knowledge in particular is warranted by direct experience unaffected by social conditions. At most, the philosophies concede that extra-theoretical factors influence the genesis of ideas but not the structure or the validity of thought (context of discovery). Otherwise, quite different epistemologies—for example, that of Karl Popper (1902–1994)—have shared a rejection of the possibility of a sociological analysis of knowledge, particularly scientific knowledge, and warned against any relativism, not only in science but also for society, that was seen as associated with the modern sociology of knowledge.

The modern sociology of knowledge, by contrast, investigates the interconnections between categories of thought, knowledge claims, and social reality—that is, the *Seinsverbundenheit* (existential connectedness) of thought described by Karl Mannheim (1893–1947). Karl Marx (1818–1883) was a significant precursor of the field, with his theory that, at least under certain historical conditions, economic realities ultimately determine the ideological “superstructure” by way of various socioeconomic processes. Émile Durkheim (1858–1917), too, is an important pioneer of the sociology of knowledge, even though he failed to develop a general model of the classificatory process. He argued, especially in *The Elementary Forms of the Religious Life* (1912) and *Primitive Classification* (1903, written with Marcel Mauss [1872–1950]), that the basic categories that order perception and experience (space, time, causality, and direction) derive from the social structure, at least in simpler societies. Durkheim, Mauss, and also Lucien Lévy-Bruhl (1857–1939) examined the forms of logical classification of “primitive” societies and concluded that the basic categories of cognition have social origins. However, they were not prepared to extend this kind of analysis to modern societies.

The sociology of knowledge owes its decisive development to the work of Max Scheler (1874–1928), Alfred Weber (1868–1958) (the *freischwebende Intelligenz* or “free-floating intelligentsia”), and especially Mannheim in the 1920s. It may be seen as the symptomatic intellectual expression of an age of crisis, and the recognition of its own rootedness in social structure and determination by social factors is perhaps its most characteristic trait. The mood of the German historical and social sciences during the period in which the sociology of knowledge developed in Germany may be described as one of “tragic consciousness.” Georg Simmel’s (1858–1918) view of the “tragedy of culture,” as well as Max Weber’s (1864–1920) assertion that an inescapable process of rationalization leads to the disenchantment of the world and to new forms of bondage, are symptomatic expressions of a period in which historians, philosophers, and especially social scientists argued intensely about the issues raised by historicism, relativism, philosophical skepticism, and the pervasive distrust in *Geist*.

It was during this period that the sociology of knowledge emerged as an analysis of the regularities of those social processes and structures that pertain to intellectual life and to modes of knowing (Scheler) and as a theory of the existential connectedness of thought (Mannheim). Both orientations distance themselves from the Marxist critique of ideology, which sees ideologies as mystifying
representations of social reality and as disguises of the interests of powerful groups in society. The sociology of knowledge, by contrast, is concerned with intellectual and spiritual structures as inevitably differently formed in different social and historical settings (Mannheim).

Scheler first introduced the term *Wissenssoziologie* (sociology of knowledge) in the early 1920s, and in *Problems of a Sociology of Knowledge* (1926) he provided the first systematic introduction. Scheler extended the Marxist notion of substructure by identifying different “real factors” (*Realfaktoren*), which, he believed, conditioned thought in different historical periods and in various social and cultural systems in specific ways. These “real factors” have sometimes been regarded as institutionalized instinctual forces, and as representing an ahistorical concept of superstructure. Scheler’s insistence on the existence of a realm of eternal values and ideas limits the usefulness of his notion of real factors for the explanation of social and cultural change.

Mannheim provided the most elaborate and ambitious programmatic foundation for a sociological analysis of cognition. Like Scheler, Mannheim extended the concept of substructure, suggesting that biological factors, psychological elements, and spiritual phenomena might take the place of primary economic relations in the substructure, but (just like the dominant theory of science) he did not think that scientific and technical knowledge could be subjected to sociological analysis. He conducted research into the social conditions associated with different forms of knowledge, and some of his studies are still considered first-rate examples of the kind of analysis that the sociology of knowledge is capable of. In addition to *Ideology and Utopia* (1929), these include Mannheim’s studies of competition as a cultural form, of conservative thought, of the problem of generations, and of economic ambition.

Mannheim believed that the sociology of knowledge was destined to play a major role in intellectual and political life—particularly in an age of crisis, dissolution, and conflict—by examining sociologically the conditions that give rise to competing ideas, political philosophies, ideologies, and diverse cultural products. He persistently pursued the idea that the sociology of knowledge is somehow central to any strategy for creating a rapprochement between politics and reason, and this pursuit connects his various essays in the sociology of knowledge. But Mannheim’s conception of the specific ways in which such a sociology might affect the state of political knowledge fluctuated and changed. There are three main versions: (1) sociology of knowledge as a pedagogical but also political mode of encountering and acting on the forces making up the political world; (2) sociology of knowledge as an instrument of enlightenment related to the dual process of rationalization and individuation identified by Max Weber and comparable to psychoanalysis, acting to set men and women free for rational and responsible choices by liberating them from subservience to hidden forces they cannot control; and (3) sociology of knowledge as a weapon against prevalent myths and as a method for eliminating bias from social science, so that it can master the fundamental public problems of the time and guide appropriate political conduct.

The sociology of knowledge has recently experienced a reorientation in the direction of an analysis of everyday life and of natural scientific and technical knowledge. Peter Berger and Thomas Luckmann’s *The Social Construction of Reality* (1966), written in the tradition of Alfred Schutz’s (1899–1959) phenomenology and Arnold Gehlen’s (1904–1976) philosophical anthropology, represents a clear departure from the preoccupation of the classical sociology of knowledge with issues of epistemology, methodology, or ideologies. Everything that is regarded as knowledge in society is now accepted as a legitimate subject matter for sociological investigations.

Inspired by developments in the history and epistemology of science—by, for example, Thomas Kuhn (1922–1996)—the sociology of knowledge in the 1970s turned in the direction of empirical analyses of the social construction of scientific facts, frequently by way of ethnographic studies of laboratory life. Such research on the “manufacture” of natural-scientific knowledge has led to a reassessment of traditional assumptions about the unique rationality of scientific knowledge. Seen through the lens of the “strong program” of the sociology of knowledge, scientific knowledge and everyday knowledge are in fact extraordinarily similar. In general, the cognitive turn in the sociology of knowledge has had little impact on science or the so-called division between the two cultures (C. P. Snow [1905–1980]) in the scientific community. Moreover, the sociology of scientific knowledge has been criticized from within the field of science and technology studies as reductionist, as overemphasizing the role of controversies in science, and as stressing a universe of inquiry that is void of nonhuman entities (e.g., instruments, measuring devices, laboratories).

The sociology of scientific knowledge also has encountered a strong reproach from philosophers of science and scientists who attempt to overcome doubts and skepticism engendered by a sociological analysis of science by placing knowledge on a firm, uncontested foundation, even outside the realm of sociohistorical experience. The dispute about the apparent attack by sociology on the validity and objectivity of scientific knowledge culminated in the 1990s in the so-called science wars. Sociologists were accused of favoring a stance of anything
Sociology, Latin American

goals. In the end, the social nature of science and its role in society remain essentially contested.

SOCIOLOGY, LATIN AMERICAN

Sociology did not gain a foothold in Latin America until after World War II when Latin American universities opened sociology departments. Latin American sociology has, in general, a number of features that make it distinct from U.S. or European sociology. First, Latin American sociologists have been concerned with understanding issues of poverty and inequality. In general, they have been less concerned with value-neutral research than with research that is concerned with analyzing and improving the quality of life for the poor. As the Brazilian sociologist Fernando Henrique Cardoso stated, “The intellectuals in Latin America are important because they are the voices of those who cannot speak for themselves” (Kahl 1988, p. 179).

The scholar Alejandro Portes pointed out that in contrast to North American or European sociologists, Latin American sociologists are frequently marginalized, having little access to government and/or private institutions that fund research in wealthier nations. He also noted that the intellectual and political commitments of Latin American sociologists mean that they are frequently the first academics to suffer under authoritarian regimes. For example, sociology was outlawed in Cuba following Fidel Castro’s revolution in 1959 and in Chile following the military coup d’etat of 1973. In the 1980s and 1990s, sociology made a strong comeback in Latin America in sync with its return to democracy.

DEPENDENCY THEORY

Latin American sociologists are probably best known for dependency theory, a school of loosely Marxist thought that arose in the 1960s and 1970s as a critical response to modernization theory. In the 1950s and 1960s, modernization theory was the dominant approach to questions of third world development. It was the policy prescribed by the United Nations and informed by the work of U.S.-based academics. In essence, modernization theory argued that underdeveloped countries, such as those in Latin America, could develop along lines similar to the United States and other developed countries in Europe. Raúl Prebisch, an influential Argentine economist, noted that the policy prescriptions of the modernization theorists were flawed because underdeveloped countries were exporting raw materials (agricultural products and minerals) with declining rates of profit while they imported finished goods from advanced countries that were more expensive every year.

Drawing on the work of Prebisch, but also Gino Germani, an economist based in Argentina, Latin American sociologists began developing dependency theory as a critical response to modernization theory. Dependency scholars argued that the underdevelopment of the third world was generated by the expansion of capitalism in advanced countries. That is, first world development occurred at the expense of the third world. Thus, underdeveloped countries could not follow the path of advanced countries because they lacked another set of countries to exploit; in addition, they could not compete with the more advanced economies and firms of the first world.

There were two schools of thought in dependency theory. The first, associated with the work of André Gunder Frank (but also Celso Furtado and Theotonio dos Santos), is considered the radical version of dependency theory. These scholars emphasized that third world economies were bound to stagnate because first world firms repatriated profits gained in the third world. Thus, third world countries would never benefit from opening their countries to multinational corporations. Consequently, they recommended either socialist revolution or autarky; that is, delinking from the global economy as the best means to promote national development. Critics of dependency theory have been quick to point out that this strategy, seen in cases such as Cuba and North Korea, has failed.

A second strand of dependency theory, associated with the work of Cardoso and Enzo Falletto, suggests a
much less radical view. These scholars argued that external constraints (competition in a global capitalist market) and internal factors (such as class relations and political alliances) explain the trajectory of individual third world countries. They argued that “associated dependent development” was possible; that is, that less developed countries could have simultaneously participated in the global economy and improved the lives of their citizens. In essence, national leaders enjoyed more room to maneuver than the radical dependency scholars allowed.

VARIANTS OF DEPENDENCY THEORY
In addition to the aforementioned scholars, the work of the Mexican Pablo González Casanova should be discussed. His widely read book *Democracy in Mexico* (1970) offers a complex portrait of the ruling PRI party (Party of the Institutional Revolution) in Mexico. González Casanova acknowledged the advances made by the PRI (including land reform and a booming economy). However, he pointed out that a growing number of people, especially the indigenous, were left out of the PRI’s benefits. González Casanova noted that the indigenous were experiencing what he called “internal colonialism,” which acknowledges that they had traded one set of colonial powers (the Spanish) for a new one (the Creole-Spanish descendants who ruled Mexico after the War of Independence). González Casanova offered a critique of the PRI, calling for a democratic opening from within the party so that more Mexicans could benefit from its legacy.

Dependency theory played an important role in Latin American intellectual life, influencing the thought of activists in the liberation theology movement and in the United States among scholars of third world development. Dependency theory faced criticisms on the one hand from Marxists, such as the scholar Robert Brenner, who in the late 1970s underscored that dependency theorists betrayed an implicit intellectual tie, not to the German political philosopher Karl Marx but to the Scottish economist Adam Smith. Mainstream scholars criticized dependency theory because it failed to explain the trajectory of a number of newly industrialized countries (such as Hong Kong, Singapore, South Korea, and Taiwan). That, in combination with the eclipse of the Soviet Union in 1989, suggested dependency theory was doomed for the dustbin of history. In fact, a parting shot was provided by Cardoso himself, who was elected president of Brazil from 1995 to 2003 and implemented policies that differed greatly from the positions he outlined earlier in his academic career.

While the more radical variants of dependency theory have been abandoned, in the 2000s the theory is somewhat influential among scholars of development, much to the chagrin of its critics. As Portes noted in his reflection on sociology in Latin America in 2004, radical dependency theory was easily rebutted by the course of history; however, radical neoliberal development policies should also be criticized for their poor results, including increasing levels of inequality and the immiseration of the working class.

SOCIOLGY, MACRO-

Macro-sociology is an approach to the scientific study of social life that focuses upon the large-scale social patterns of human behavior. Societies are considered as totalities, with a particular emphasis on major institutions of social life, such as the economy, the political system, the family unit, and systems of religious belief. Macro-sociology is typically concerned with the systematic examination of the major similarities and differences among societies, in particular the nature and scope of the changes that societies undergo.

Methodologically this tends to mean that macro-sociological studies focus upon a single society in a single given historical period, adopting large-scale surveys as a way of gathering data. However, many macro-sociologists have an abiding concern with how such social systems are interlinked across the world and in particular how single societies change over time. Historical-comparative methods are thus frequently used in analyzing how social systems within a given society, for example, the United States, have changed and developed throughout the nation’s history.
Macro-sociology is often regarded as standing in opposition to micro-sociology. Micro-sociology typically investigates the patterns of thought and behavior that occur in relatively small-scale social groups, with a particular emphasis on different styles and codes of verbal and nonverbal communication. Micro-sociologists analyze the ways face-to-face interaction is managed and maintained and how this helps develop shared understandings within social groups. However, in the early twenty-first century this distinction is increasingly called into question as the micro-foundations of macro-sociology are made explicit (Alexander et al. 1987; Sanderson 1995). Nevertheless, macro-sociological approaches continue to play a part in international social science research, and two of the most prominent approaches are structural functionalism and conflict theory.

Structural functionalism sees societies as complex social systems of interrelated and interdependent parts that shape and influence each other. These different parts of the social system are interrelated by a commitment to the norms, values, and beliefs that integrate the entire system, which structural functionalists believe tends toward a state of equilibrium. As such, disturbances to any one part of society will require adjustments elsewhere in order for balance to be restored and for the system to avoid disintegration. Each interrelated part of the social system exists therefore precisely because it has a vital function to perform in helping to maintain the equilibrium of the system as a whole.

Conflict theory stands in opposition to structural functionalism by typically rejecting the idea that societies tend toward a state of equilibrium. This is based upon the belief that societies do not share a basic consensus over norms, values, and beliefs that operate in everyone’s best interest. Rather, conflict theorists point to the various ways different individuals and social groups have competing and antagonistic interests and concerns and emphasize that these basic oppositions shape the organization of social life.

In the early twenty-first century macro-sociology is less influential in international social science than it once was. Nevertheless, it continues to provide an important foundation for approaching the study of human social life, especially in contemporary sociological theory.

**SOCIOLGY, MICRO-**

The study of group dynamics and interaction is often termed microsociology. There are many different areas investigated within microsociology, and there are different perspectives and methodologies. The area can be broadly conceptualized as considering issues related to self and identity, status and power, cooperation and competition, exchange, legitimation, and justice.

The self is one of the most important concepts in microsociology, particularly in the general perspective of symbolic interaction. The self, as distinct from the psychological conceptualization of the personality, is fluid and adaptive to context. So the roles that an individual must fulfill might require him or her to be very structured in one context and very flexible and adaptive in another context. From the symbolic interaction perspective, individuals learn to define themselves in large part based upon how others see and interact with them. In this way individuals are constantly assessing and projecting different identities to themselves and others. This makes interaction fundamental to self-identity. Research within this area has focused on both qualitative and quantitative investigations of such topics as role taking, altercasting, identity disruptions or deflections, and self-referent behavior.

Group interactions themselves or types of encounters with others constitute other aspects of microsociology. Cooperation and competition were some of the earliest topics in microsociology, and they have endured in their importance. Early studies of group cohesion and identity were featured in Émile Durkheim’s study of suicide, for example. More recent developments in the area examine differing incentive structures that lead toward or against cooperation. Much of this work has focused on social dilemmas, settings in which there is a conflict between individual short-term incentives and overall group incentives. Such dilemmas range from those found in dyadic relationships to larger groups such as those involved in collective movements.

Sometimes implicated in the level of cooperation and conflict or competition are characteristics of the individuals or of their positions within the group. Status is usually defined as a position in a social network, and the investigation of the development, maintenance, and diminishment of status has been pivotal in examining how groups organize and how resources are allocated. Commonly
examined aspects of status are diffuse status characteristics such as ethnicity or sex and specific status characteristics such as accounting ability or ability to score soccer goals. Allocation of different resources is studied within exchange formulations, and the resulting assessments, behavior, and feelings of fairness are the focus of justice and equity formulations. Related to assessment of justice is the degree of acceptance of particular institutional arrangements or legitimation.

Microsociology incorporates many types of research methods, including case studies, documentary–historical studies, ethnomethodology, participant observation studies, surveys, and experiments. A particularly promising trend in research is the examination of the interrelationships between micro and macro phenomena. These developments do not begin with the assumption that either the micro or the macro cause the other; rather, they investigate how the different levels affect and are affected by each other.

SOCIOLOGY,
PARSONIAN

Talcott Parsons was an American sociologist whose work dominated English-speaking social theory from the end of World War II (1939–1945) until the mid- to late 1960s. Parsons elaborated a general theory of society believing that it would give sociology a distinctive subject matter of its own, while also securing a scientific status for the discipline alongside those other social sciences concerned with the activities of the individual as a member of a group. Parsons's work focused attention on the power of the social system to influence the social behavior of individuals.

THE PARSONIAN PERSPECTIVE

In Parsons's view, the primary task of sociology is to develop a set of abstract generalizing concepts capable of describing the social system. This provides all investigators with a common conceptual framework for empirical work in order to enable cumulative inquiry. These generalizing concepts are to be judged through their rational coherence as a basis for then making propositions about the world. Parsons's first major publication, The Structure of Social Action (1937), reviewed the work of some European theorists, namely Max Weber (1864–1920), Émile Durkheim, Vilfredo Pareto, and Alfred Marshall, whose works, Parsons claimed, converged around basically "the same system of generalized social theory … the voluntaristic theory of action" (p. 720). This theory views human beings as making choices between ends (or goals) and means (or ways) of achieving particular ends. These choices, Parsons argued, are limited by shared values contained within the social environment. It is because individuals embrace values concerning the sacredness of human life and the family that tendencies towards pure self-interest are curbed and the need for external sanctions including legal punishments are reduced, though never totally eliminated. These values are expressed through concrete norms, or rules of behavior, which limit the lengths to which individuals will go when pursuing their chosen ends or goals.

Parsons's early critical investigation of the work of classical European sociologists provided a foundation for his later work, The Social System (1951), which asked, "how is order possible?" Parsons argued that values and normative expectations provide the context in which actors seek to maximize their personal desires. Behavior and relationships that facilitate the achievement of individual needs and desires become institutionalized into a system of status roles and sanctions that are articulated through the social system. The social system, in turn, includes a personality system (the individual actor) and a cultural system (broader values that make sense of the norms linked to status roles). These three systems form the general theory of action. Each system is linked to a functional prerequisite or set of needs that must be met in order for the system as a whole to continue working. Pattern variables are also closely bound up with this general theory of action. They refer to the choices that actors must make between alternative options as a necessary condition for meaningful action in any given situation. Pattern variables are important because they classify actors' modes of orientation in the personality, social, and cultural systems. This theory also provided the foundation
for Parsons’s concept of structural functionalism, which attempted to categorize any level of social life at any level of analysis.

INFLUENCE ON SOCIOLOGICAL THEORY
Parsons’s major works have influenced the development of sociological theory in a number of ways. *The Structure of Social Action* introduced American sociologists to the work of Durkheim and Weber as general theorists, which not only established a common vocabulary for modern sociologists but also provided them with an important frame of reference. Parsons’s analysis of convergence in the works of certain European theorists also set a precedent for other sociologists, for example Anthony Giddens, to make links between oppositions such as conflict/consensus, action/structure, and micro/macro in contemporary social theory. *The Social System* helped develop and further a systems analysis, or large-scale macro, approach in sociology in place of one that stressed the importance of individual or micro elements.

The dominance of Parsons’s ideas in sociology declined around the mid- to late 1960s. A resurgence of interest in Parsons’s work took place, however, in the 1980s. Jeffrey Alexander in the United States and Richard Münch in Germany, for example, attempted to build upon and resolve certain problems implicit in Parsons’s original systems theory through their own distinctive works on neofunctionalism. The theory of neofunctionalism stresses the need to bring together action theory and systems theory while also emphasizing the key importance of collective or macro phenomena in establishing the conditions within which social action takes place.

Critics of Parsonian sociology have focused on its failure to engage with practical reality and empirical social problems. Parsons’s work has been stigmatized as merely grand theory. Parsons’s excessive concern with the power of the social system also led certain critics to argue that he saw human beings as oversocialized conformists whose individual behavior was largely determined by system constraints. Other commentators have suggested that Parsons’s emphasis on social integration, conformity, and harmony disregarded inequalities and those material interests, power, and ideological elements that supported them.

SOCIOMETRY, POLITICAL
In a seminal article from 1969, Giovanni Sartori drew a sharp distinction between the sociology of politics and political sociology. The sociology of politics, Sartori argued, involved a reduction of politics to its social conditions and thus formed a subfield of sociology much like the sociology of religion or of the family. While a comprehensive analysis of political institutions and processes certainly would involve an analysis of social conditions, the sociology of politics was insufficient, Sartori argued, because it lacked political science’s understanding of politics in its own terms and as a fundamental activity. Sartori’s solution was thus that political sociology should be a genuine hybrid, though his main concern was to defend against “sociologists eager to expand to the detriment of political scientists” (1969). More interesting, however, was Sartori’s argument that the reason this synthesis was so important was that the objective role of politics was increasing and hence the necessity of political analysis for larger social theory was as well: “The power of power is growing at a tremendous pace,” he wrote. As a result, “the greater the range of politics, the smaller the role of ‘objective [read sociological] factors’” (1969).

It is perhaps ironic, then, that virtually the only scholars who regularly use the term sociology of politics today are political scientists, when they want to highlight social variables, such as class or family structure. Political sociology is indeed usually used to refer to a subfield of sociology, but one that has long since adopted the kind of hybrid approach Sartori thought sociology lacked. Political sociologists thus study an array of political processes in their own terms, in terms of their social conditions, distributions, and effects, and in terms of their
combination of these two sides. Moreover, in light of the robust theories of power that have developed since the late 1960s in virtually all varieties of social theory, political sociology has long since abandoned any clear separation of the social from the political.

The intellectual roots of political sociology reflect its cross-disciplinary reach from a time even before disciplines. The philosophers of classical antiquity, for instance, wrote extensively about the varieties of political possibility, including kingship, aristocracy, and, most important for modern discourse, democracy. But the ancients did not yet have a clear concept of society, such that politics and society could be seen to interpenetrate and covary in interesting ways. This conceptualization awaited the thinkers of the European Enlightenment, who theorized society as distinct from, but shaping and shaped by, political institutions. Thus Montesquieu (1689–1755) proposed a theory emphasizing the role of climate in shaping the basic forms of governance—republican, monarchical, and despotic; behind each of these forms was a particular “spirit,” comprising the distinct manners and morals of people living in these particular conditions. A. R. J. Turgot (1721–1781), Condorcet (1743–1794), and others—perhaps most importantly the great Scottish economist Adam Smith (1723–1790)—advanced historical accounts emphasizing different aspects of social and economic development that corresponded to transformations in basic forms of governance. Jean-Jacques Rousseau (1712–1778) in particular introduced the contemporary notion of civil society, and outlined the ways in which the “General Will” of the collectivity might be propagated through “political religion.”

Like their predecessors, social thinkers in the nineteenth and early twentieth centuries—the forerunners of contemporary political sociology—variously developed broad explanations by reconstructing the historical process, theorizing its motors, and delineating the features of key contemporary social structures and institutions. While a wide variety of thinkers—including philosophers, economists, politicians, natural scientists, and sociologists—contributed to the development of political and social thought in this period, Karl Marx (1818–1883) and Max Weber (1864–1920) have been the most important for the subsequent development of political sociology.

Beyond the political effects of his work, Marx’s legacy for political sociology consists mainly in his approach to “political economy,” which nevertheless in many respects most clearly embodies the reductionistic “sociology of politics” approach Sartori bemoaned. Because Marx saw the “material”—including the means and relations of production—as the key foundation for social forms, including the state, Marxist political sociology has always emphasized the basis of all politics in economic interests (though the “economic” has sometimes been understood more narrowly, and sometimes more broadly). In the Marxist tradition, the modern state is thus conceived as an expression of the “interests” of the ruling class—the bourgeoisie. Nevertheless, the Marxist tradition—always more complex than either its denigrators or doctrinaires portrayed it—has evolved important accounts of the complex relations between state and civil society in the capitalist and postindustrial eras, of the state as a powerful player in class conflict, as well as an emphasis on the role of power, both economic and political, in the process of social reproduction.

Usually taken as a contrasting figure, Max Weber also developed a powerful account of social stratification in capitalism. But for Weber, disparities in wealth were not the only driving force behind this stratification; rather, differences in status and political power also came into play, potentially forming complicated groupings not reducible to class. In contrast to orthodox readings of Marx, Weber held that in modern times political institutions have become separated from economic and social structure, and thus developed a powerful analysis of the state as an agent and product of bureaucratic rationalization. Perhaps most famously, Weber developed a typology of political power, distinguishing traditional, bureaucratic, and charismatic legitimation as ideal types. In his pessimistic account of modernization, Weber traced a general trend toward bureaucratic rationality tending toward complete domination—the so-called iron cage—though the move from traditional to bureaucratic legitimation was punctuated, and would likely continue to be, by moments of charismatic consolidation. Over time, however, this charismatic authority also succumbed to the rationalization process, what Weber termed “the routinization of charisma.”

While many-faceted, three legacies in particular define Weber’s influence on political sociology: first, his broad comparative-historical method; second, his multidimensional theory of class, status, and party, which is usually taken as a refutation of Marxist reductionism; and third, his analysis of the bureaucratic operation of the state as part of his overall account of the “rationalization” process. One subsequent development adapting elements of Weber’s theory was the theory of “the circulation of elites” by Gaetano Mosca (1858–1941), which emphasized the power exercised by competing small groups with superior knowledge and technical expertise, as well as the trenchant analysis of political parties as organizing forces of these elites by Robert Michels (1876–1936). But these are only two prominent immediate examples, and nearly all political sociology since Weber has manifested various residues of and engagements with his thought.
In the United States during the twentieth century, scholars in political sociology continued the traditions established by Marx and Weber, among other nineteenth-century thinkers, of conceptualizing their subject matter in broad, macrohistorical terms. For the two decades following World War II (1939–1945), political sociology thus reflected the broader division in sociology between functionalism and conflict theory.

Amalgamating insights developed by Émile Durkheim (1858–1917) into the forms of social solidarity with Weber’s account of rationalization, as well as more traditional Anglo-Saxon liberal political thought, functionalism created a model of reality in which various social institutions exist in and sustain an orderly interrelated whole. A facet of this whole was a perceived clear analytical distinction between state and society, a perspective expressing the liberal outlook of this school. Political parties, according to this view, were the major institutions connecting state and society. A central aspect of this agenda, particularly as applied by political scientists, was the comparison between liberal-democratic regimes and communist regimes, in terms of multiple interrelated spheres of polity, economy, society, and culture. The functionalist approach to national socialism and communism, for instance, was associated with the theory of “totalitarianism,” which was drawn in distinction to Marxist accounts that portrayed “fascism” as an extreme outgrowth of capitalism; totalitarianism theory saw the Nazis and the Soviets as one type, while fascism saw them as distinct. Where fascism theory gave overwhelming precedence to the economic sphere, functionalism saw “totalitarian” states as polycratic, and ascribed their power to homologies among analytically distinct societal subsystems. In less dramatic and politically charged efforts, functionalist research investigated “political culture”—first the norms and values that supported particular political institutions, then a later more interpretive analysis of political symbols and meanings—as well as topics relating to American institutions, such as the bureaucracy, media and information, the military, and political parties.

In contrast to functionalism, conflict theory borrowed basic tenets from Marx and many of its variants are characterized as “Marxist,” particularly those that take a critical stand on the connection between social science and political action. Not all conflict theory is Marxist, however, since one can accept on purely analytical grounds that conflict is pervasive in social and political life. Nevertheless, holding conflict to be paramount, conflict theory questioned functionalism’s emphasis on order and individual autonomy from politics. Social order, for conflict theorists, was not the result of functional interdependence but, where present, the outcome of competing social forces. Conflict theorists thus charge that the liberal separation between state and society was unfounded, and pursued an analysis of many different bases of conflict, including race and gender along with class and other factors.

In contrast to the Manichean distinction between conflict and functionalist perspectives in the 1960s and 1970s, the theoretical landscape since then has been more inclusive of diverse theoretical perspectives. Beginning in the 1970s, then, and continuing in the 1980s and 1990s, political sociology developed a variety of thematic orientations, as opposed to building and defending a few grand theoretical positions. Thus new research agendas emerged. One such agenda argued that the state should be the central subject of comparative sociological and political inquiry. Studies in this vein examined the historical formation of the state with renewed comparative focus on states as autonomous actors with their own interests, while other studies put the state’s organizational profile under comparative scrutiny.

A somewhat different research agenda was one that had primarily concerned historians earlier: the study of nationalism. While the methods and ideological orientations of studies of nationalism varied, they tended to have a broad historical scope that sought the genesis of what was usually taken to be a modern phenomenon.

A third research agenda regarded questions of economic-political development around the world, including differential patterns of development. Dominated by so-called dependency theory and world-systems theory, this approach produced a wide array of findings that, though typically having a historical outlook, found a place in more standard debates in sociology and comparative politics.

Yet a fourth research agenda gaining momentum during this period was one that focused on social movements and collective action—to many, the quintessential topic for political sociology. Though a key impetus for the spread of this research agenda was the interest in investigating the civil rights movement of the 1960s, research on social movements grew to cover diverse geographical, political, and historical contexts. Finally, a fifth research agenda pertained to the conceptualization and historical evolution of civil society and its related concept of social capital. Again, with considerable divergence in terms of theoretical and political vantage points, this line of inquiry has attracted attention from sociologists, political scientists, and historians, as well as philosophers and political practitioners, particularly since 1989, when political sociologists saw the development of a vibrant public sphere between the individual and the state as the linchpin of democratization after the collapse of communism in Eastern Europe.

Perhaps the most important topic toward which social scientists in general and political sociologists in particular
have turned their attention since the 1980s is globalization. Referring in general to increasing economic, political, and social interconnectedness across the world, globalization puts many of the traditional concerns of political sociology in a new context. In the face of the expansion of global trade and investment capital, political sociologists have become interested in examining the repercussions of unequal global development, global inequality, and, more generally, the social adjustment to economic change. Political sociologists have extended this critical view to developments in the West as well, such as the spread of neoliberal ideology and the resistance to it through various antiglobalization social movements and other forms of protest. Further, political sociology has adjusted its traditional concerns in the face of emerging political global actors. Thus political sociologists are investigating the role of transnational corporations, nongovernmental organizations, and political and economic intergovernmental organizations. One theme that ties such various facets of investigation together is the question of the challenge these emerging actors pose to the maintenance of the state’s modern form. In the face of globalization of culture, finally, political sociology revisits traditional concerns regarding identity, values, political loyalty, citizenship, and migration patterns. Under the influence of poststructural and postmodern theory, political sociology has inquired into the complex processes through which the basic units of its analysis are “constructed” as political actors and entities, including through the disciplinary practices of sciences like political sociology itself.

SOCIOLOGY, POST-PARSONIAN AMERICAN
Talcott Parson’s functionalism became the dominant paradigm in American sociology after World War II. Talcott Parsons (1902–1979) envisioned society as a coherent and auto-regulating social system separated from its environment by boundaries. A social system itself consisted of relatively autonomous but also interdependent subsystems responsible for the general functional imperatives of adaptation, goal attainment, integration, and latency. Functionalism held that social systems tended toward equilibrium, change being slow and evolutionary, oriented toward increasing complexity and differentiation. Robert Merton had already criticized his mentor’s penchant for grand theorizing and assumption of systemic unity and integration in Social Theory and Social Structure (1949). This book distinguished between latent and manifest functions in social systems and stressed the unintended consequences of action. But Merton himself, in many respects, operated within the functionalist paradigm, which lost its hegemony only in the late 1960s and the early 1970s. While functionalism had for at least two decades unified sociology with an overarching theoretical framework, competing paradigms emerged as both a cause and a result of its decline. American sociology became much more heterogeneous, pluralistic, and contentious. The main strands of post-Parsonian sociology are reviewed below. Research that is either theory driven or has theoretical implications for the discipline as a whole are privileged in this survey.

CONFLICT AND DOMINATION
A significant group of American sociologists attacked the integration and consensus premises of functionalism and made conflict and domination in society their focus. Inequality and its social reproduction have also become crucial issues. The politically charged environment of the 1960s undergirded this paradigm shift, and many sociologists took their cues from Karl Marx and Max Weber. Eric Olin Wright rejuvenated the classical Marxian theory of exploitation and class by taking into account not only control over the means of production but also control over how things are produced and control over labor power. Other Marxists, such as Michael Burawoy, studied accumulation processes and class conflict on the shop floor. Alvin Gouldner pointed to the ascent of a new social class formed by the cognitive elite. William Julius Wilson elucidated the logics of economic and racial inequality in the United States, and Douglas Massey dissected the segregation patterns in American cities.

In addition to class and race, gender also became a central research area. Nancy Chodorow’s The Reproduction of Mothering (1978) combined psychoanalysis with
sociology to examine gender dynamics in the nuclear family. Arlie Hochschild studied the feminine nature of emotional work in contemporary society, and Christine Williams undertook ethnographies of gender relations in the workplace. Domination and conflict also stimulated sophisticated theoretical work, such as Steven Lukes’s influential treatise on power. The most ambitious theoretical form of conflict sociology has been provided by Randall Collins, who developed over the decades a potent model to study (among many other things) credentialism, geopolitical strife, and intellectual transformation. It is a testament to the empirical soundness of his general conflict model that Collins successfully predicted in the 1980s the breakdown of the Soviet empire.

HISTORICAL-COMPARATIVE SOCIOLOGY

Another strand in the post-Parsonian period focused on wide-scale historical transformations. In contrast with the evolutionary and integrative assumptions of functionalism, the burgeoning field of historical-comparative sociology mostly centered on dynamic political and economic structures and underlined the role of revolution, violence, and contention in social change. Barrington Moore’s seminal book *The Social Origins of Dictatorship and Democracy* (1966) outlined the three routes to the modern world (the liberal, the fascist, and the communist) and the mechanisms through which preindustrial agrarian social structures and the course of industrialization mixed to determine regime outcomes. His student Theda Skocpol fashioned a robust theory of social revolution based on state structures, international forces, and class relations.

Immanuel Wallerstein’s world-system theory pushed the capitalist division of labor to the global level and examined how the countries in the periphery are exploited by those at the core. Daniel Bell hailed the rise of postindustrial society. He also pointed to the contradictions between the economic and the cultural logics of late capitalism. Charles Tilly created models of contentious politics and state formation; his argument about the positive feedback between state making and war making has attained classic status. In the last decade of the twentieth century he also put forth relational theories of violence and inequality. Michael Mann has been fleshing out since the mid-1980s the interconnections between economic, political, ideological, and military power throughout history, and Jack Goldstone has significantly improved the understanding of revolutions by stressing demographic pressures on states and the role of intra-elite conflict. It is important to note, however, that not all cutting-edge historical-comparative sociology has been about politics. William J. Goode’s *World Changes in Divorce Patterns* (1993), for instance, constructed an ambitious theory to cross-culturally analyze and predict divorce.

SOCIAL STRUCTURES AND ORGANIZATIONS

Formal properties of social structures and organizations constituted the main research objects for the third sociological strand in the post-Parsonian era. The Simmelian geometry of social forms was an inspiration to many scholars. In the 1970s Donald Black developed a general social control approach, which he subsequently applied to behavior of law, formation of norms, coalition building, economic consolidation, and deviance. Harrison White’s famous study of vacancy chains made a momentous contribution to the literature on organizational forms and mobility. Mark Granovetter’s work on the strength of weak ties was decisive in making network analysis a major methodology in sociology. Network analysis has been successfully operationalized since the 1970s to depict and explain phenomena as disparate as collective action, organizational behavior, cultural and scientific diffusion, sexual behavior, and crime. Among the most brilliant practitioners in sociology are Peter Bearman, Ronald Burt, Roger Gould, Edward Laumann, and John Padgett.

Post-Parsonian sociology took an interest in both the formal and the symbolic structures of organizations. Prominent representatives of the neo-institutionalist perspective, Paul DiMaggio and Walter Powell analyzed organizational isomorphism, John Meyer and Brian Rowan considered the mythical and ceremonial dimensions of formal structures in organizations, and Frank Dobbin showed the effects of cultural meanings on industrial policy. There has also been considerable theoretical progress in research on social systems. Andrew Abbott, for instance, proposed an ecological model for studying professions in *The System of Professions* (1988). Abbott viewed ecology, in the Chicago tradition of urban sociology, as an interacting system, and he empirically showed how jurisdictional battles between professions have molded their individual trajectories. Abbott has also laid out an innovative research agenda with a stress on the radical temporality of all social phenomena, and he has created a fractal model to explain social change and even the development of sociology itself. Finally, functionalism itself underwent an overhaul after Parsons. The neo-functionalism of Jeffrey Alexander insisted on open-ended, pluralistic, and creative interactions between subsystems in society and added a conflict orientation to the Parsonian paradigm.

CULTURE

The fourth sociological strand after Parsons was spurred by the linguistic turn in the social sciences. Culture became a key concept, especially in the 1980s and the
1990s. Ann Swidler has claimed that, rather than being preferences or values, culture involves strategies of action incorporated in dispositions, styles, and skills. Bill Sewell worked out a semiotic model of action and a theory of social structure integrating both resources and transposable schemes. His theoretical work explores temporality and underscores the importance of events in the transformational social structures. Viviana Zelizer showed how social meanings govern economic interactions and how people use money to create and maintain intimate ties. Michelle Lamont emphasized the role of symbolic boundaries and moral vocabularies in social stratification. Alexander’s cultural sociology highlighted the centrality of meaning systems and performative practices in civil society.

**MICRO-SOCIOLOGY**

Finally, concomitant with the studies of large-scale structures, institutions, and processes, the post-Parsonian era also witnessed a growing interest in micro-sociology. Two distinct micro paradigms challenged functionalism's vision of the “oversocialized concept of man,” to use the words of Dennis H. Wrong (1961). The first of these is interactionism. The symbolic interactionism of Herbert Blumer argued that meaning is construed through social interaction and that individuals are interpretative beings with reflexivity. Howard Becker's labeling theory as well as his later groundbreaking work on art worlds followed, in many respects, the symbolic interactionist research program. In his work resisting all facile theoretical labels, Erving Goffman was probably the most important student of social interaction in the second half of the twentieth century. From the late fifties to his untimely death in 1982, he analyzed social interaction in all kinds of settings using a wide array of dramaturgical, game-theoretic, etiological, and cognitive concepts. His studies of impression management, stigma, role distance, embarrassment, and total institutions have all become classics.

Again within the interactionist paradigm, Harold Garfinkel deployed ethnomethodology to uncover the practical and often unconscious rationality that guides quotidian routines, with a particular attention to how people give accounts. Conversation analysts have devised sophisticated tools to capture the logic of verbal interaction. Among signal work in the interactionist tradition are Jack Katz’s subtle phenomenological analyses of violence and emotions and Randall Collins’s theory of interaction rituals, which is exceptionally promising as it bridges the individual and institutional levels.

Utilitarianism has been the other major micro-paradigm in the post-Parsonian era. This paradigm itself consists of two interacting streams: exchange theory and rational choice theory. George Homans had already done behaviorist work in the 1950s on social exchange. Peter Blau later extended Homans’s model by exploring the structural implications of exchange, and Goode built on this paradigm to examine the production and distribution of prestige in society. The ways power relationships affect social exchange have been extensively investigated by Richard Emerson and Karen Cook. Parallel to these developments in exchange theory, an increasing number of researchers (usually referred to as rational-choice sociologists) were drawn to the promise of explaining social interaction and institutions from the assumptions of utility-maximizing actors and methodological individualism. These scholars were influenced by the work of economists such as Mancur Olson, who studied in the 1960s and the 1970s the collective action problems that groups face. In this vein Michael Hechter attempted to account for group solidarity from rational choice premises. James S. Coleman’s magnum opus *Foundations of Social Theory* (1990) strived to erect a parsimonious rational choice foundation to explain all kinds of phenomena, including social capital, trust, collective action, and revolutions. Coleman applied his model also to the asymmetry between natural and corporate actors in contemporary societies.

As noted, the post-Parsonian period has been characterized by a multiplicity of theoretical orientations. While some have seen this as a cause for concern, there is reason to think that it is the absence of a hegemonic paradigm like the Parsonian functionalism that has allowed for the immense dynamism in the late twentieth century and early twenty-first century and that both the productive exchanges and the contentious struggles between the different strands sketched above have vastly enriched American sociology.

**BIBLIOGRAPHY**

SOCIOLOGY, RURAL

The discipline of rural sociology addresses how communities and areas with few people are socially and economically organized, what patterns of social interaction occur among residents within these areas and elsewhere, and why and how communities change over time. Its early practitioners were active members in the rural sociology section of the American Sociological Society (later renamed as the American Sociological Association) until 1937. In that year, they founded the independent Rural Sociological Society (RSS) to promote teaching, research, and extension outreach. Since then, membership in the Society increased from seventy-nine to slightly less than one thousand academic scholars, professionals, and students in the new millenium. The first newsletter of the rural section appeared in 1925. The RSS published the newsletter as Newsl ine from the 1970s through 1980 and subsequently as The Rural Sociologist with the purpose to spread news about the vitality of rural sociology among its practitioners and others interested in the discipline.

HISTORICAL CONTRIBUTIONS

Rural sociological scholarship has a long tradition involving people, communities, and natural resources due in part to its location in the university land-grant system. In 1997 Norwood Kerr discussed the founding of the American land-grant university system by the Morrill Land-Grant College Acts of 1862 and 1890, the latter for traditionally black institutions in southern states. These acts introduced the movement led by Connecticut and thirteen other states to establish agricultural experiment stations to specifically address the development of practical agricultural information for rural farmers and ranchers through scientific investigations. The movement culminated in 1887 with the passage of the Hatch Act that forged the federal-state partnership for funding “scientific agriculture.” The public service counterpart to the Hatch Act followed in the Smith-Lever Act of 1914. It assigned the new cooperative extension service the task providing to ordinary people access to their state universities for assistance regarding a broad array of issues affecting themselves, and their families, businesses, and local governments. Early rural sociology programs and their research were and continue to be mostly affiliated with institutional partnerships between universities and agricultural experiment stations along with cooperative extension both at the state level and with counterparts in the United States Department of Agriculture.

Following the pioneering work of sociologists such as W. E. B. Du Bois and F. H. Gidding, rural sociology was significantly influenced by the Country Life Commission that was appointed by President Theodore Roosevelt. The Commission’s 1909 report on twelve rural communities pointed to problems of poverty, crime, population change, and governance that many rural communities were experiencing at that time and revealed the need for the land-grant system to devote social science expertise to solve these problems. Funding for conducting this research languished for a while, but passage of the Purnell Act of 1925 expanded federal commitment to experiment station research by funding studies in agricultural economics, rural sociology, and home economics. As documented by Olaf Larson and Julie Zimmerman in 2003, this commitment was extended in the United States Department of Agriculture (USDA)’s Division of Farm Population and Rural Life, where rural sociologists such as Charles Galpin, Carl Taylor, and others pioneered national-level studies on social trends and conditions in rural areas. These studies were followed by more locally oriented studies conducted by academic rural sociologists such as Paul Landis, Carle Zimmerman, and Dwight Sanderson. Founded in 1936, the journal Rural Sociology became the flagship for reporting much of this research.

During the next quarter-century, the importance of rural sociology to the public policy process and programs diminished with the dismantling of New Deal programs in the 1940s and the Division of Farm Population’s successor, the Bureau of Agricultural Economics (BAE), in 1953. The USDA no longer favored what it termed “cultural surveys” nor did it receive well Walter Goldschmidt’s study of two rural California communities in 1944 wherein he reported that rural well-being was negatively affected by large farms and powerful farmers. Trends of an increasingly more urban and industrialized U.S. population in the post–World War II (1939–1945) era were among other factors that contributed to rural sociology’s loss of stature.

CONTEMPORARY RESEARCH EMPHASES

Interest renewed in rural sociology in the last quarter of the twentieth century. Researchers continued their traditional interests in rural communities, population change, rural poverty, and social inequality. They rejuvenated work begun in the 1950s on the adoption and diffusion of agricultural innovations. In 1983 Everett Rogers, one of the foremost leaders of this area, reported that the number of empirical studies grew from a total of 405 in 1962.
to slightly more than 3,000 twenty years later. The “sociology of agriculture” became the new label that drew on this research history. It also staked out new areas regarding the social significance of women in agriculture, new biotechnologies, the expansion of industrialized agriculture and agribusiness, and the globalization of agro-industrialized systems. In their 1988 book, Rural Sociology and the Environment, Don Field and William Burch Jr. recognized important connections among agricultural sociology, human ecology, and natural resource sociology. They termed the intersection of these research venues as “agroecology” (p. 114) and proposed that it serve in the broadest sense as a definitive guide for rural development and a critical component of applied environmental sociology. The most comprehensive inventory of rural sociological concepts, subject matter, and knowledge about American rural life appeared in 1997. Gary Goreham’s The Encyclopedia of Rural America: The Land and People includes articles by prominent rural sociologists and other scholars on 232 topics that vary from agriculture and other rural industries to rural youth, the elderly, women and minority groups, crime, culture, technology, and natural resources and the environment.

INTERNATIONAL RURAL DEVELOPMENT

Community and economic development continue to be important research and policy issues that confront and connect rural communities and rural scholars in America and abroad. Economic globalization has stressed and challenged rural communities everywhere. While many businesses and manufacturing companies seek out lower-cost production areas and lucrative markets, rural communities strive to find ways to overcome infrastructural, capital, resource, and policy obstacles to promote development and competitiveness. In 1962 U.S. and European rural sociologists convened at the annual meeting of the RSS in Washington, D.C., to form the Committee for International Cooperation in Rural Sociology to address these issues.

After three world congresses, the Committee organized the International Rural Sociology Association (IRSA) in 1976 to spearhead concern and attention involving the impacts of globalization and rural development. The IRSA is a federation of regional rural sociological societies devoted to foster the development and application of rural sociological inquiry to improve globally the quality of rural life. In addition to the RSS, the Association includes the Australian and Oceania Network, the Asian Rural Sociological Association, the Latin America Rural Sociological Association, and the European Society for Rural Sociology. The IRSA met at the XI World Congress in 2004 in Trondheim, Norway, to explore the unevenness, risks, and resistance related to the globalization of production and to the identification of rural economies’ and societies’ agency to manage change in this process. IRSA congresses are held every four years.

SOCILOGY, SCHOOLS IN

In this entry, school will be understood as referring to a group of practitioners who are identified in terms of characteristic ways of acting upon the world. Such practices are derived from some general principles (analytical, theoretical, empirical premises of interpreting and putting into
practice some basic ways of viewing reality), often formulated by a central figure or figures and amplified by their students or followers. If not in terms of some defining orientation to the world, a school may receive its identity in terms of either the name of the leader who formulated the basic approach, or else the setting where the group developed its coherence and overall unity.

Schools are fairly common categorizations of groups in the humanities, such as in philosophy (e.g., American pragmatism), the arts (e.g., cubism), and even history (e.g., the Annales school of Lucien Febvre [1878–1956], Marc Bloch [1886–1944], and Fernand Braudel [1902–1985]). In contrast, it is uncommon to find schools in the history and development of the natural sciences, however marked they are by controversies over priorities in scientific discoveries. In between, although it is more common in presenting the history of the discipline to deal with the work of individuals rather than that of schools, in the social and behavioral sciences (social anthropology, clinical and social psychology, and particularly sociology), schools have played a major role. To pursue this topic, however, it is necessary to provide further specification of what is taken to be a school by breaking the term into a weak sense and a strong sense.

By weak sense of school is meant a grouping of figures and their research and publications that share a general orientation to reality, a general way of dealing with and interpreting social reality, irrespective of whether these individuals have known or interacted with each other; the strength of their networks is thus weak, and there is no specific locale for their training. The collective identity of such a school is heuristic in providing some organization to the diversity of empirical and research orientations present in the discipline, but it does not have a clear focus. And school in this sense may fade into a looser grouping, such as traditions that may be analytical (e.g., Collins 1994) or geographical (e.g., Genov 1989).

Perhaps the best approach to schools in the weak sense noted above is the pioneering study of then-contemporary sociological theories conducted by Pitirim Sorokin (1889–1968). He proposed (1928, p. xvi) that social theories seeking scientific merit could be grouped in nine major schools (mechanistic, synthetic and geographical, geographical, biological, biosocial, biopsychological, sociological, psychological, and psycho-sociological), with some important varieties listed under several schools. The taxonomy of his study was intended to establish inductively and critically sociology as a multidimensional discipline seeking to deal factually with its subject matter and correlations between classes of social phenomena and between social and nonsocial phenomena. Fifty years later this perspective of the unity in diversity of sociology still held (as seen in Eisenstadt and Curelaru 1976).

Strong schools are those that have a recognizable central primary figure (or in some cases, figures) who elaborates the basic principles of approaching social reality in the search for valid knowledge (the ontology and epistemology of the research enterprise)—metaphorically, who prepares the basic structure of a cookbook of recipes that may be used by students. In turn, the practices of the students add to the corpus of the initial doctrines and principles, perhaps by taking this into new vistas of research. The networking among members of the school will be strong, and will often show a high degree of citation of works of one another, with the writings of the central figures given privileged attention. While cohesion and mutual support vis-à-vis the discipline is high, for example, in obtaining resources for members and new recruits, such as publication outlets, research grants, and even academic or related positions, it is by no means assured. Yet even strong schools may weaken after one or two generations, either due to internal bickering regarding leadership or intellectual direction, or because of apparent exhaustion of research potential in the basic formulations of the school. Ultimately, the appeal of a school may wane when its central problems and modes of operation become viewed as superannuated in relating to societal reality and its changing conditions.

Some strong schools at peak strength dominate subfields of sociology and take on the general name of their orientation, with subgroups as offings having their own identity. In social psychology-sociology, symbolic interactionism (coined by Herbert Blumer [1900–1987]) has stressed the significance of establishing and interpreting how actors make sense (find meaning) in interacting with one another, even if the objective meaning of their situation is ambiguous. This school, drawing on the initial theoretical writings of the pragmatist philosopher George Herbert Mead (1863–1931) and the pioneering social psychological studies of William J. Thomas (1863–1947), had new dimensions introduced in the 1960s and 1970s in the ethnographic studies of Erving Goffman (1922–1982) and Harold Garfinkel (the latter, aided by Aaron Cicourel, developing the frames of ethnomethodology), and further in the 1980s in the studies of Gary Fine on subcultures. Though it is still a viable orientation at the microlevel (of interacting individuals), it has not been an overarching orientation of broader segments of society.

Also in this rubric of strong schools might be included world-system theory, which in the 1970s and 1980s had a major formulator, Immanuel Wallerstein (assisted by Terence Hopkins and Chris Chase-Dunn), a center for training (at the State University of New York—Binghamton), and a journal (Review). The comparative-historical studies of this school derive from a Marxist perspective of the exploitation of labor, before as well as after the advent of modern capitalism, and the unequal
distribution of world resources operating over time in zero-sum fashion with core capitalistic countries accumulating greater shares at the expense of “peripheries.” The emergence of India and East Asia in recent decades has attenuated the appeal of this school, although it has made with its many scholars an important mark in the area of macrosociology.

There is perhaps a further set of very strong schools, which have practically dominated the entire field of sociology, or at least established some sort of intellectual hegemony for an entire generation or more. One might speak of the Marxist school drawing on the leadership of Karl Marx (1818–1883) and Friedrich Engels (1820–1895), with a basic presupposition that the social order rests on the expropriation of labor and the exploitation of workers, who are temporarily kept from realizing their true conditions by the smokescreens of the dominant class, but as conditions increasingly worsen, a point will be reached where a socialist revolution will shatter the capitalist system. There have been numerous variations of Marxism claiming legitimacy as successors, but the one that in addition to world-system theory has been most recognized in the United States and Germany is the Frankfurt school, which later evolved under the second-generation leadership of Jürgen Habermas (at the University of Frankfurt) as critical theory. The major figures of the school in the 1920s sought to amalgamate a Marxist orientation critical of capitalism (historical materialism) with a Freudian orientation on psychological and cultural maladaptations of the modern world that hinder personal freedom and generate alienation. At the Institute of Social Research, they—notably Theodore Adorno (1903–1969), Max Horkheimer (1895–1973), and Herbert Marcuse (1898–1979)—pursued philosophical and historical investigations, interrupted by the Nazi regime. After World War II (1939–1945), the renovated critical theory orientation found many adepts on both sides of the Atlantic, spearheaded by Habermas, who engaged in the mass media a wide variety of topics and whose writings on communicative action considerably widened the theoretical tools by an earnest engagement with non-Marxist orientations such as American pragmatism and Parsonsian action theory.

The three other “hegemonic schools” (Tiryakian 1986) to be noted may each be said to have nearly dominated the field of sociology, either in their own country or in the entire discipline. Besides all the characteristics of strong schools noted above, they emerged in periods of national reconstruction following some major crisis, and their basic theoretical and methodological orientations offered new initiatives for sociological action.

The secular government of the French Third Republic (1870–1940), which gave a high premium to public education, science, and civic morality, favored the rise of the Durkheimian school (Besnard 1983), whose intellectual leader, Émile Durkheim (1868–1917), produced foundational works for modern sociology, established the teaching of sociology at the prestigious Sorbonne in Paris, attracted highly gifted students—Marcel Mauss (1872–1950), François Simiand (1873–1935), Maurice Halbwachs (1877–1945), Marcel Granet (1884–1940), Robert Hertz (1881–1915), Henri Hubert (1872–1927)—who later found appointments in major areas of the public sector, and secured major publishing outlets (the publishing house Alcan and the world-class journal, the Année Sociologique, which greatly contributed to advancing comparative-historical sociology and tacitly is the model for the American Annual Review of Sociology). The school emphasized in diverse analyses the irreducibility of the social to individual causation such as economic interests, but sought to bring to light structures of social organization deeply imbedded in cognitive and ritual aspects of the collectivity itself.

In the United States, the University of Chicago became the locale of a new empirical orientation derived from (1) the pragmatism of Charles Sanders Peirce (1839–1914), William James (1842–1910), and George Herbert Mead (1863–1931), and (2) the application of ecology in botany to the study of the dynamics of social organization of the human urban habitat, marked by competition and accommodation of various groups. With brilliant students under the analytical leadership of Robert Park (1864–1944) and the quantitative leadership of his lieutenant, Ernest Burgess (1886–1966), the Chicago school emerged after World War I (1914–1918) as providing outstanding training in field research and participant-observation of interaction processes (Bulmer 1984; Abbott 1999; Chapoulié 2001). It obtained research grants for its students, enjoyed a major publication outlet for doctoral monographs with the University of Chicago Press, and has been the site of the continuous publication of a world-class journal, the American Journal of Sociology.

Finally, in the post–World War II era, from the mid-1940s until the mid-1960s, Talcott Parsons (1902–1979) at Harvard University provided the prolific intellectual leadership for a new and systematic analytical perspective intended to integrate sociology, social anthropology, and social and clinical psychology. As the United States took global leadership in a pax Americana, Harvard’s Department of Social Relations provided new comparative and theoretical training that could be applied at micro- as well as macrolevels of analysis in what came to be termed structural-functional analysis. The historical development of this school and some of its major contributors—including Robert Merton (1910–2003), Kingsley Davis (1908–1997), Neil Smelser, and Robert Bellah—as related to but distinct from Parsons (whose later writings
in what he saw as “action theory” went considerably beyond the initial mode of analysis he provided in the 1940s and 1950s (awaits to be written, beyond Parsons’s intellectual biography (Gerhardt 2002). Such a history would entail the many resources the school made available (such as the publishing house the Free Press, and the research grants of the Ford Foundation) and the diffusion of many of its central theoretical ideas to related disciplines such as political science and social anthropology.

This necessarily skeletal account of schools needs two final points. First, some of the most important names in the history of sociology are not associated with schools, despite their intellectual worth and significance. Such is the case, for example, with Herbert Spencer (1820–1903), Max Weber (1864–1920), Georges Gurdvitch (1894–1965), and Pitirim Sorokin. Second, schools do not flourish in sociology at all times; the contemporary period, for instance, seems to be a quiescent period bereft of a clearly recognized “hegemonic” school. Perhaps this presents an opportunity for a more objective examination of the rise and fall of schools, as well new research on their interconnecting networks.

SOCIOLOGY, THIRD WORLD

Any discussion of the “third world” should begin with a definition of the term. Third world is commonly used to describe countries that are economically poor, lack adequate educational and health systems, suffer from the digital divide, and exhibit relatively little global political power. Although frequently used, the term is considered out-of-date and even derogatory in some circles. Many scholars, for instance, argue that “third world” implies that poor countries are less important than other (“first world”) countries or are somehow not part of the global economic system. In their 2007 book Global Inequalities, York Bradshaw, Stephen Scanlan, and Michael Wallace said that instead of “third world” critics often use “developing world” or “developing nations” when referring to countries that are not fully developed from an economic and quality of life standpoint.

In his 1974 publication The Modern World System, Immanuel Wallerstein discussed one theoretical perspective concerned with development, which places countries into three different categories. The “core” is composed of rich, industrialized countries that also enjoy a relatively good quality of life in terms of education and health care. The “periphery” is composed of poor countries that lack industrial capacity and well-developed education and health care systems. The “semi-periphery” is composed of middle-income countries that are between the core and the periphery. The periphery and the semi-periphery make up the vast majority of the world's countries.

For this discussion, terminology is not a main concern. Terms come and go over time, but the reality is that global inequality remains an enormous problem. Much of the world lives amid extreme poverty. This article describes the developing world and then discusses how sociology studies it.

AN UNEQUAL WORLD

To begin, here is a quiz: What two developing countries account for 37 percent of the world’s 6.5 billion people? If you answered China (1.3 billion) and India (1.1 billion), you win a prize. In fact of the ten most populated countries in the world, seven are considered developing and,
together with China and India, they account for nearly 51 percent of the world’s population. Of the 210 countries listed by the World Bank, three-quarters are considered low- or middle-income countries, and this represents the vast majority of the world’s population. In fact, if the issue is studied in reverse, there are only twenty-four true “core” countries in the world (11 percent of the world’s countries), and they account for less than 20 percent of the global population. There are a number of other “high income” countries (e.g., Bahrain, Kuwait, Monaco, Slovenia), but they are mostly small and do not possess all of the characteristics of the core (World Bank 2007).

Another way to think about global inequality is to compare the resources of companies, countries, and individuals. Here is another quiz: What country has the twenty-second largest economy in the world, as measured by gross domestic product (output of total goods and services)? The answer: the core country Austria, which has a gross domestic product of $309.4 billion. Twenty-one countries have larger economies, and 188 have smaller ones (World Bank 2007). But wait a minute! Austria is not the twenty-second largest economic entity in the world; Wal-Mart is. That is right. According to Christopher Tkaczyk in his 2007 article “Fortune 500: The Top 50,” Wal-Mart, the biggest multinational corporation in the world in terms of total revenue ($351.139 billion), is larger than all but twenty-one countries in the world. Wal-Mart is larger than several core countries, most semi-peripheral countries, and all peripheral countries. And incredibly the combined revenues of the top two multinational corporations (Wal-Mart [$351.139 billion] and Exxon Mobil [$347.254 billion]) are greater than the combined economic output of all fifty-three sub-Saharan African countries. Together Wal-Mart and Exxon Mobil are larger economic entities than the entire continent of Africa (Tkaczyk 2007; World Bank 2007).

Inequality is also evident when looking at personal wealth across countries and regions. A comprehensive study conducted in 2006 by the World Institute for Development Economics Research at the United Nations University in Helsinki, Finland, revealed that the richest 2 percent of the world’s population owns more than half of the world’s wealth. And the richest 10 percent of the population owns 85 percent of the world’s wealth. By contrast, the bottom 50 percent of the world’s population owns 1 percent of the total wealth on the planet. In fact 1.3 billion people around the world live on less than $1 per day, and 3 billion (nearly half the planet’s population) live on less than $2 per day. By contrast, pointed out Luisa Kroll and Allison Fass in the 2007 article “The World’s Billionaires,” the extremely wealthy of the world—the 946 billionaires throughout the globe—are worth $3.5 trillion ($3,500,000,000). That is more than twice the gross domestic product of all peripheral countries in the world combined (World Bank 2007).

And what are the consequences of poverty? One is disease and premature death. A primary development indicator is the child mortality rate in a country—the number of children who die before the age of five for every 1,000 children born. In economically developed countries, the average child mortality rate is only 8 (led by Sweden’s 3), but in developing countries the rate is 89. In a pair of 2007 studies by UNICEF, it was found that in Africa the child mortality rate is 174, with a number of countries over 200 and some approaching 300 (UNICEF 2007a, 2007b). Each day around the world as many as 35,000 children die primarily from preventable diseases and malnutrition. Respiratory infections, diarrheal disease, tuberculosis, measles, malaria, and HIV/AIDS are some of the leading causes of death among children of the developing world. According to York Bradshaw, Stephen Scanlan, and Michael Wallace (2007), the vast majority of the world’s HIV/AIDS cases are in developing countries, led by African countries.

SOCIOMETRY AND GLOBAL INEQUALITY

Sociology was slow to study international inequality and development. Until the 1970s the field was dominated by economists, anthropologists, and political scientists. All of this began to change in 1974, when the sociologist Immanuel Wallerstein published The Modern World System. Wallerstein argued that the current world economic and political structures have their origins in sixteenth-century Europe. His book and subsequent work established an entirely new theory (world-systems theory) that divides the world into the core, periphery, and semi-periphery, as mentioned previously. Although some people disagree with Wallerstein, just about everyone agrees that along with finding an innovative theory, he started a movement of young sociologists who wanted to study international inequality and development.

In response to Wallerstein’s new theory, a number of sociologists began to conduct sophisticated statistical studies to examine the causes and effects of international inequality. The results of several studies are presented below. All are based on a large sample of developing countries.

- Foreign investment in poor countries does not reach the mass population and therefore creates more inequality in those places. This ultimately harms economic growth in the developing world (Bornschier and Chase-Dunn 1985).
- Expanding foreign debt and the accompanying structural adjustment policies implemented by the
International Monetary Fund (IMF) and others increase child mortality in poor countries (Bradshaw, Noonan, Gash, and Buchmann 1993).

- Likewise structural adjustment policies have increased riots and overall instability in a number of developing countries (Walton and Ragin 1990).
- Education is linked to greater economic growth and less inequality in the developing world (Buchmann and Hannum 2001; Hannum and Buchmann 2005).
- Child labor is detrimental to the quality of life in developing countries. Moreover education reduces child labor, again underscoring the necessity of schooling in developing nations (Bradshaw, Scanlan, and Wallace 2007).

Sociologists use two other types of studies to advance theoretical and substantive knowledge of development. First, some sociologists compare a few countries in great detail in order to address difficult questions and issues that often reflect inequalities of wealth and power. For example, in his book Reluctant Rebels: Comparative Studies of Revolution and Underdevelopment (1984), John Walton looked at revolts and revolutions in the Philippines, Colombia, and Kenya to answer this question: Why and when do people rebel? And in the book Child Labor in Sub-Saharan Africa (2004), Loretta Bass takes us across the continent of Africa to explain the causes and effects of child labor (including slavery). Inequality is again a key component in the explanation of this pressing challenge. Second, other sociologists engage in intensive case studies of particular developing countries to investigate especially important issues (Bradshaw and Wallace 1991). For example, in his highly regarded book Underdeveloping the Amazon: Extraction, Unequal Exchange, and the Failure of the Modern State (1985), Stephen Bunker relied on extensive fieldwork to show how local and international forces interacted to plunder the Amazon. And in Growing Up Modern: The Western State Builds Third-World Schools (1991), Bruce Fuller focused on the poor country of Malawi to demonstrate how the “fragile” national state tried (with mixed success) to implement a Western-style education system. National and global inequalities helped to explain the outcome.

In the early twenty-first century most internationally oriented sociologists are concerned with global inequality in one form or another. Although an occasional sociologist argues that global inequality is shrinking and globalization is a positive force (see, for example, Glenn Firebaugh’s provocative book The New Geography of Global Income Inequality [2003]), most are concerned about the high level of inequality and its impact on the vast majority of the world’s population. In terms of offering solutions to global inequality, sociologists have joined others to advocate for more foreign aid to poor countries and forgiveness of the developing world’s crippling debts. Perhaps the most well-known and passionate spokesperson for these positions is Bono, the lead singer for the Irish rock group U2. He has encouraged the United States and other countries to contribute 1 percent more of their federal budgets to the world’s poor:

One percent is the girl in Africa who gets to go to school—thanks to you. One percent is the AIDS patient who gets her medicine—thanks to you. One percent is the African entrepreneur who can start a small family business—thanks to you. One percent is not redecorating presidential palaces and money flowing down a rat hole. This one percent is digging waterholes to provide clean water. (Bono 2007, p. 41)

There is much more for sociologists to study. Over the next ten years sociologists will most likely devote substantial attention to three issues (among others). First, HIV/AIDS continues to ravage large parts of the developing world, and there is a huge need for research to study both the causes and effects of this pandemic in more detail. Second, information technology has the capacity to improve health, education, and overall quality of life in developing regions (Bradshaw, Fallon, and Viterna 2005). Commenting on a new e-school initiative in Africa, South African president Thabo Mbeki said, “Let us use this technology to do things better, develop African brain power that will pull our country and the African continent as a whole out of poverty” (Nepad 2007). Finally, many believe that the darkest side of globalization includes not the sale of products across national borders but the sale of human beings. Hundreds of thousands of people—especially women and girls—are sold each year in both the developing and the developed worlds. Sociologists are primed to lead the way in studying this enormous social challenge, another problem that emerges from an unequal world.

Sociology, Urban

SOCIOLGY, URBAN

As the cutting edge of change, cities are important for interpreting societies. Momentous changes in nineteenth-century cities led theorists to explore their components. The French word for place (bouyg), and its residents (bourgeois), became central concepts for Karl Marx (1818–1883). Markets and commerce emerged in cities where “free air” ostensibly fostered innovation. Industrial capitalists thus raised capital and built factories near cities, hiring workers “free” from the feudal legal hierarchy. For Marx, workers were proletarians and a separate economic class, whose interests conflicted with the bourgeoisie. Class conflicts drove history. Max Weber’s (1864–1920) The City (1921) built on this legacy but added legitimacy, bureaucracy, the Protestant ethic, and political parties in transforming cities. Émile Durkheim (1858–1917) similarly reasoned historically, contrasting traditional villages with modern cities in his Division of Labor (1893), where multiple professional groups integrated their members by enforcing norms on them.

British and American work was more empirical. British and American churches and charitable groups that were concerned with the urban poor sponsored many early studies. When sociology entered universities around 1900, urban studies still focused on inequality and the poor. Robert Park (1864–1944) and many students at the University of Chicago thus published monographs on such topics as The Gold Coast and the Slum (1929), a sociological study of Chicago’s near north side by Harvey Warren Zorbaugh (1896–1965).

The 1940s and 1950s saw many efforts to join these European theories with the British and American empirical work. Floyd Hunter published Community Power Structure (1953), an Atlanta-based monograph that stressed the business dominance of cities, broadly following Marx. Robert Dahl’s Who Governs? (1961) was more Weberian, stressing multiple issue areas of power and influence (like mayoral elections versus schools), the indirect role of citizens via elections, and multiple types of resources (money, votes, media, coalitions) that shifted how basic economic categories influenced politics. These became the main ideas in power analyses across the social sciences.
Parisian theorists like Michel Foucault (1926–1984), Pierre Bourdieu (1930–2002), and Henri Lefebvre (1901–1991) suggested that the language and symbols of upper-status persons dominated lower-status persons. Others, such as Jean Baudrillard, pushed even further to suggest that each person was so distinct that theories should be similarly individualized. He and others labeled their perspective postmodernism to contrast with mainstream science, which they suggested reasoned in a linear, external, overly rational manner. Urban geographers like David Harvey joined postmodernist themes with concepts of space to suggest a sea change in architecture, planning, and aesthetics, as well as in theorizing, although Harvey’s main analytical driver is global capitalism.

Saskia Sassen starts from global capitalism but stresses local differences in such “world cities” as New York, London, and Tokyo. Why these? Because the headquarters of global firms are there, with “producer services” that advise major firms, and market centers where sophisticated legal and financial transactions are spawned. Individual preferences enter, via global professionals and executives who like big-city living, but hire nannies and chauffeurs, attracting global migrants, which increases (short-term, within city) inequality. Some affluent persons create gated housing, especially in areas with high crime and kidnapping, like Latin America.

These past theories stress work and production. A new conceptualization adds consumption. Walter Benjamin (1892–1940) theorized that the flâneur drove the modern capitalist economy, by shopping. Typified by the top-hatted gentleman in impressionist paintings, the flâneur pursued his aesthetic sensitivities, refusing standardized products. Mall rats continue his quest.

Theories have grown more bottom-up than top-down, as have many cities, although this is controversial, as some capital and corporations are increasingly global. The father of bottom-up theory is Alexis de Tocqueville (1805–1859), whose Democracy in America (1835–1840) stressed community associations like churches. Linked to small and autonomous local governments, these associations gave (ideally) citizens the ability to participate meaningfully in decisions affecting them. Such experiences built networks of social relations and taught values of participation, democracy, and trust.

In the late twentieth century, Tocqueville and civic groups became widely debated as nations declined and cities competed for investors, residents, and tourists. With the cold war over, globalization encourages more cross-national travel, communication, investment, and trade. Local autonomy rose. But nations declined in their delivery of egalitarian welfare benefits, since ideal standards are increasingly international. “Human rights” is a new standard. Yet the world is too large to implement the most costly specifics, even if they remain political goals.

Over the twentieth century, many organizations shifted from the hierarchical and centralized to the smaller and more participatory. The community power literature from Hunter (1953) to Dahl (1961) and beyond suggests a decline in the “monolithic” city governance pattern that Hunter described in Atlanta. Dahl documented a more participatory, “pluralistic” decision-making process, where multiple participants combine and “pyramid” their “resources” to shift decisions in separate “issue areas.”

New social movements (NSMs) emerged in the 1970s, extending past individualism and egalitarianism and joining consumption and lifestyle to the classic production issues of unions and parties. These new civic groups pressed new agendas—ecology, feminism, peace, gay rights—that older political parties ignored. In Europe, the national state and parties were the hierarchical “establishment” opposed by NSMs. In the United States, local business and political elites were more often targeted. Other aesthetic and amenity concerns have also arisen—like suburban sprawl, sports stadiums, and parks; these divide people less into rich versus poor than did class and party politics.

Comparative studies emerged after the 1980s of thousands of cities around the world. They have documented the patterns discussed above, and generally show that citizens and leaders globally are more decentralized, egalitarian, and participatory. The New Political Culture (1998), edited by Terry Nichols Clark and Vincent Hoffmann-Martinot, charts these new forms of public decisions and active citizen-leader contacts via NSMs, consumption issues, focused groups, block clubs, cable-television coverage of local associations, and Internet groups. Global competition among cities and weaker nations makes it harder to preserve national welfare-state benefits. This encourages more income inequalities, individualism, and frustrated egalitarianism, which is registered in higher crime rates, divorce, and low trust. As strong national governments withdraw, regional and ethnic violence rises (e.g., in the former Soviet Union or diverse cities like Miami). Voter turnout for elections organized by the classical national parties (which still control local candidate selection in most of the world) thus declined, while new issue-specific community associations mushroomed in the late twentieth century. Urbanism has become global, carried by civic groups, diffused by the Internet, and operating in more subtle ways than past theories proposed.

Sociology, Voluntaristic vs. Structuralist

Voluntaristic sociology emphasizes the importance of free will, or agency, in social settings. Structuralist sociology emphasizes the importance of social settings in shaping and constraining free will. Tension between the two emphases has bedeviled and inspired sociology and related disciplines since the nineteenth century. Among the first to wrestle with this tension was Auguste Comte, who coined the term sociology in the 1830s. Human action is determined by the laws of society, in Comte's structuralist view, but understanding these laws will allow sociologists to help modify human action. Comte recognized the possible contradiction and discussed it in lecture 48 of his Social Physics ([1839] 1975, p. 132): if free will is able to make modifications, “what can [they] consist of, since nothing can alter either the laws of harmony or the laws of succession?” Comte's solution reflects his structuralist emphasis: free will can affect only the intensity of the operation of societal laws, not the laws themselves. Comte gives examples of powerful monarchs who had only a meager impact on the lives of their subjects.

Later scholars expanded the scope of voluntarism beyond monarchs and sociologists to encompass all of humanity. The most extreme statement of voluntarism within the sociological mainstream came from Herbert Blumer, who invented the term symbolic interactionism in 1937. Human behavior, Blumer insisted, is a creative act that cannot be reduced to structural causes: “even though it may well be a well-established and repetitive form of social action, each instance has to be formed anew” (1969, p. 17). This formulation implies that people may choose not to behave as expected. Indeed, while symbolic interactionism generally focuses on conformity, Blumer also helped to establish the field of collective behavior, which focuses on deviance. In these writings Blumer argued that voluntaristic deviance, if it comes to be widely accepted, is the main mechanism through which societies evolve.

By the end of the twentieth century, voluntarism had, in one sense, conquered the field. It was considered improperly derogatory to imply that any person's choices are determined by social context. Even explicitly structuralist theories were increasingly concerned to accommodate free will to some degree, often through the use of the concept of opportunities. At the same time, the goal of most sociological explanation remained structuralist, focusing on contextual factors that predict individual outcomes. The radical voluntarism of symbolic interactionism and collective behavior analysis was not widely adopted and, indeed, came to be criticized for ignoring the persistent structures of inequality that characterize social life. In short, sociology was equally committed to voluntarism and structuralism. This paradox generated a variety of attempts to view structure and agency as mutually constitutive.

On one hand were efforts at combination. An influential version of this approach was Peter L. Berger and Thomas Luckmann's The Social Construction of Reality (1966), which argued that the two moments of institution—creation and institution—maintenance are analytically distinct even if they may in practice coincide. The creation of institutions involves the active working of human agency while maintenance involves the socialization of future generations to view the institutions created by their predecessors as legitimate and permanent. A contrasting approach is exemplified by Anthony Giddens's The Constitution of Society (1984), which argues that structure and agency should not be considered as distinct from one another but, rather, as two parts of the same process, which he labeled structuration. People produce and reproduce the rules of social life in ways that are patterned by the rules of social life.

On the other hand were efforts to privilege structuralism over voluntarism and vice versa while maintaining both. A sophisticated version of the former balance comes from the works of Pierre Bourdieu. Bourdieu argued that human agency is a variable product of social structure mediated by the bodily comportment and criteria of judgment that Bourdieu called habitus. Habitus structures individual preferences and actions and is itself structured by training within particular social contexts. Claims of agency—whether among academic observers or the people being observed—are in this view the result of structural processes. Alternatively, voluntarism may subsume structuralism, as in Patricia Hill Collins's Black Feminist

Sociometry

Collins argued that the powerless are frequently canny observers of the workings of society and active agents of resistance. Ongoing subordination is the product of other people's continuous efforts to dominate, and even the powerless participate in this “matrix of domination” when they work to protect their privilege, meager as it may be (Collins 2000, pp. 227–229, 273–277). The implication is that structuralist claims—whether among observers or the observed—are voluntaristic acts of domination that obscure the radical potential of voluntaristic transformation.

These approaches are usually cited as a way of signaling intellectual affiliation and are only beginning to be juxtaposed and compared. It remains unclear what standards one might use to evaluate voluntarism and structuralism.

SOCIOMETRY

Sociometry, by definition, measures the “socius”—the interpersonal connection between two people (Moreno 1951). The founder of sociometry, Jacob L. Moreno (1889–1974), conceived three levels of sociometry (Moreno [1953] 1993), applying the term sociometry to each (tending to cause confusion). These levels are:

- theoretical system (alternately termed sociatry)—including role, social atom, spontaneity/encounter, psychodrama/enactment, and sociometry theories;
- subtheory of that system; and
- assessment method and intervention (Hale 1981; Remer 2006).

Historically sociometry was a central influence in sociology and related areas, even producing several dedicated journals. Over time, though, its influence has diminished to such a point that, at most, one of its central constructs—the sociogram—gets only passing mention in assessment texts (e.g., Cohen and Swerdlik 2005; Cronbach 1970; Gronlund 1971). However, a complete understanding of sociometry provides tremendously powerful structures and tools for use not only in small group interactions but also wherever and whenever interpersonal dynamics come into play.

Grasping the entire sociometric system is optimal, but popularly sociometry theory is focused on measuring relationships, the purview of both social atom theory (long-term relationships and their development and maintenance over time) and sociometry (fluctuation of interpersonal connections over short periods). The sociogram is the representation of sociometry (see Figure 1).

Beyond the conception of humans as essentially social beings, sociometry recognizes and uses the fact that all these connections are perpetually manifest in the social choices we make—for example, with whom we eat lunch; whom we marry; whom we sit next to in classes, receptions, and other meetings; whom we like and do not like (based on tele, warm-up, role reciprocity). Using both positive (choose/acceptance/attraction) and negative (not-choose/rejection/repulsion) choices, the connections between people and the patterns of connections throughout groups are made manifest, explored, and influenced (Remer 1995a, 1995b; Remer and Finger 1995; Remer, Lima, Richey, et al. 1995).

The key to using sociometry as an assessment and intervention (like Heisenberg’s principle) most effectively is understanding Moreno’s full conceptualization. The misconception is that sociometry stops with the production of the sociogram from choices expressed related to a specific criterion (e.g., “With whom would you most and least want to sit at a wedding reception?”). This level is what Moreno called “near [weak] sociometry” (my label). “Strong” sociometry requires two conditions beyond eliciting choices and depicting them: (1) The choices must be implemented (e.g., you must sit with whom you have
chosen), and (2) the reasons for choosing must be made overt and explored. The last two conditions present many possibilities and difficulties.

Implementing the choices makes them real in the sense that the full impact of a choice is experienced (e.g., you can say I’ll sit with Aunt Bertha to be nice, but actually sitting with her may inform you fully why others have not opted for that seat). So future choices will be influenced. Arriving at an optimal implementation is challenging because not everyone can have one of his or her positives, and some must endure a negative—regardless of how many selections are allowed (a phenomenon addressed by the theory).

Examining choice rationales presents other challenges. People tend to be uncomfortable with the process because, for example, they believe that feelings may be hurt or they are confused by their own ambivalences and lack of awareness of their reasons. Reservations have some validity but usually not nearly to the degree feared. The benefit derives from probing projections attendant—assumptions about the rationales and/or expectations for the choices. At worst, some perceptions are confirmed; at best and more often, the rationales do not conform to suppositions in informative ways (e.g., you are not chosen by a friend because you see each other frequently and he or she wants to visit with others, or you are chosen by someone because you are seen as the only less talkative person in the group). Negatives are not necessarily “bad,” nor are positives necessarily “good.” Learning reasons challenges assumptions and/or provides the basis for changing behaviors—a not inconsequential therapeutic value.

The sociograms (Figure 1) and the choices from which it is constructed (Figure 2) clarify these points and introduce terminology to illustrate the strengths of sociometry. The data are real, using the criterion “From whom would you like feedback?” based on two positive and two negative choices.

The pattern of choices shows that D is the “star” (that is, he or she receives the most choices) and F is a “rejectee” (he or she receives no positive choices and a number of negative choices); everyone else is a “member” (receiving some positive and perhaps some negative choices). No “isolate” (someone receiving no choices) appears. C, D,
and E form a “subgroup,” having each reciprocally positively chosen each other. The centrality of D and F to the group dynamics is more obvious in seeing the positives and negatives separately, illustrating that energy of the group is demanded regardless of choice valence—both D and F have significant impacts.

The criterion implemented dyadically manifests practical difficulties. Who would be paired with D; who would be stuck with F? If C and E were paired, satisfying their desires, what then of D’s desires? The optimal implementation satisfies the most choices of either valence. The process makes manifest exactly the dynamics experienced in all group situations (as anyone planning a wedding reception can attest). Knowing the reasons behind the choices and their strength (expanded schema) can help with optimal assignment. Some rationales indicate that “violating” a choice is not as detrimental as assumed (e.g., A and G reciprocally reject because they do not know each other).

With the particular criterion used (and its converse, “To whom would you like to give feedback?”), the implementation and rationale-sharing fit well together (i.e., sharing the rationales is giving feedback). With different criteria the sociometry will change, perhaps not greatly. For example, “To whom would you like to speak?” or “Whom would you like to know better?” could change the valence of the A–G choices and also demonstrates the difference between “actionable” criteria and “near” sociometry ones (e.g., “Whom in the group don’t you know well?”). Choice of criteria influences the sociometry, revealing each individual’s worth if done skillfully.

Lest sociometry be thought to be only small-group focused, Moreno’s work with the U.S. Navy in forming more efficient and safer squads (Moreno 1951) and with the Hudson School for Girls, where cottages were formed and run sociometrically (Moreno [1953] 1993) were both large-scale sociometry interventions.

Sociometry as an assessment and intervention is a powerful tool. Sociometry the theory offers principles to predict and guide. More comprehensive and powerful, sociometry the system applies synergistically to the multiple foci and levels of human relatedness addressed by the interconnected subtheories.

SOFT SKILLS

Soft skills are core abilities and personal attributes that complement hard skills, that is, the technical knowledge required of an individual in the workplace. The term is often used synonymously with generic skills or social competence, though it refers in the strict sense only to key abilities that can be applied to job performance.

The term soft skills originated in the information technology sector and emphasizes the fact that soft skills are difficult to measure compared to technical skills, which have a straightforward or measurable impact on outcome. Due to the interdisciplinary character of the concept—it is used in the economic, social, and psychological sciences—a simple one-dimensional definition does not exist. There is broad consensus, however, concerning the division into intrapersonal skills and interpersonal skills. The former refer to self-regulating characteristics, such as time- and self-management, improvements in learning and performance, awareness of rights, and responsibility. The latter encompass those abilities and attitudes used in interactions with other people. Interpersonal skills can be further differentiated according to the individual’s position in the interactive situation. Firm-internal collaboration requires leadership qualities and conflict-management skills with regard to subordinates as well as successful participation in a team of peers. Communication skills and negotiation competencies are important in interactions with customers and clients and are especially required in service-related activities. The concept also comprises personal attitudes, such as self-confidence, integrity, and respect; technical abilities, such as knowledge in information and communication technology; and language proficiency, even though the latter can be measured and could equally be considered a hard skill.

For the United States, the Secretary’s Commission on Achieving Necessary Skills (SCANS) represents an extensive survey of abilities required to meet existing labor demands. Commissioned by the U.S. Department of Labor, SCANS identifies hard and soft skills that are essential in the workplace and ranks them according to the impact they have on job performance in different types of occupations. The survey also lists the most substantive literature on workplace skills for future research. A further important resource is the Occupational Information Network (O*NET), whose design reflects a systematic way to collect and analyze occupational information. Though both instruments show a similar categorization scheme at the broadest level, the term soft skills is not explicitly stated. Rather, SCANS uses the terms personal qualities and interpersonal competencies, while O*NET mainly uses worker characteristics. SCANS and O*NET constitute a relevant source for the development and success of education and training programs, job analysis, and job design that goes far beyond the description of entirely technical and cognitive skill requirements.

EMPIRICAL EVIDENCE

The first attempts at measuring personal and interpersonal competence can be traced to the triarchic concept of intelligence introduced by the American psychologist Edward L. Thorndike (1874–1949). Thorndike distinguished between abstract, mechanical, and social intelligence and thus allowed for a multidimensional investigation of knowledge and traits that relied on psychometric procedures (1920). The wide-ranging term soft skills, entailing highly personal and subjective traits and qualities, requires a sensitive analysis of assessment tools. A common standard of measurement at the national level is not yet available, and the instruments already existing at the microeconomic level vary with respect to the set and definition of the indicators they use. The information collected from group discussions, simulations, and psychometric questionnaires does not contain all dimensions of soft skills and only considers a small cohort of individuals. Much work has been done in the sector of information systems (IS). The personal and interpersonal skills of workers employed in the IS field have been evaluated using simulated work situations. The findings indicate that work experience does not have a significant effect on self-management strategies or interaction with peers and superiors. However, IS professionals perform better in managing subordinates and interacting with customers (Damien et al. 1999).

At the macroeconomic level, research focuses on the analysis of the impact of soft skills on earnings. Greg J. Duncan and Rachel Dunifon (1998) suggest that soft skills are as good a predictor of labor market success as are levels of formal education.

Interpersonal skills can also be used to explain gender and racial pay gaps (Borghans et al. 2005; Fan et al. 2005). Such skills have a particularly positive impact on the job performance of women. Studies in intergenerational mobility take account of soft skills, but the results derived so far are vague. Samuel Bowles and Herbert Gintis (2001) suggest incorporating personal attitudes that are relevant to economic success into the analysis of intergenerational mobility. The American sociologist Melvin Kohn argued in Class and Conformity (1969) that, at least for some traits, experiences are passed via a process of vertical cultural transmission. For example, parents who operate relatively independently in the workplace automatically transfer some of their self-regulating strategies to their children.
SOFT SKILLS AND POLICY

SIGNIFICANCE

With the shift in employment from manufacturing to services and with the diffusion of computer technology and information systems, the demand for soft skills in the labor market has increased. Soft skills not only affect the tools for recruitment, they also serve as a predictor for career progression if the type of occupation enforces a high level of social competence. Education programs have been adjusted as a reaction to changing workplace requirements. In addition, studies in the economics of aging emphasize the importance of soft skills as an instrument to compensate for the decline in cognitive and physical abilities with age, since social competencies remain relatively stable over one’s lifetime. Numerous surveys indicate that training in interpersonal and communication skills raises individual productivity at all levels of qualification.

In order to assess the progressive potential of soft skills by a common standard, a clear definition that explicitly refers to employment still remains to be developed. However, the effects of soft skills in the workplace have to be analyzed with caution. Though the state of research definitely justifies and stimulates further work in this area, the socioeconomic value of soft skills tends to be overestimated. A pure focus on soft skills neglects their complementary character with respect to technical knowledge.

SOLAR ENERGY

In a broad sense, most energy that individuals use is some form of solar energy. Other renewable energy sources (such as wind, hydropower, and wood) indirectly harness solar energy by using the atmosphere, oceans, and forests as solar collectors. Even exhaustible fossil fuels (oil, coal, and natural gas) are solar energy that was originally captured by plants and concentrated by geological processes into forms with high energy densities per unit of weight and volume.

In more common usage, solar energy refers to the two primary ways in which people harness and directly use solar energy using manufactured collectors: heating, and generating electricity.

Space and water heating systems for buildings can be either passive or active. Both approaches use glass to trap heat, as in a greenhouse. Passive design uses no moving parts or fluids; rather, it involves incorporating features into the siting and design of a building to take advantage of the natural solar radiation available. Such features include large windows facing south, heat-absorbent material such as brick or tile in floors and walls, and orienting a building on its site so as to maximize sun exposure.

Active heating systems use water or another liquid piped through collector units. The most common type of collector is a roof-mounted flat-plate design, consisting of an insulated glass-covered box painted black to maximize heat absorption. Water circulates in a loop between the collectors, where it is heated, and a tank, where it is stored until needed for either domestic uses or space heating.

There are two technologies for converting solar energy to electricity. Solar thermal-electric power plants (also called concentrating-solar-power, or CSP, power plants) use mirrors to gather solar radiation and focus it on a small area to produce high temperatures. The concentrating collectors may be parabolic troughs or dishes, or a system of mirrors that are spread over a wide area and that focus sunlight on a receiver at the top of a tower in what is called a power tower or central receiver system. A
fluid circulates through a receiver unit at the parabola's focal point, where it is boiled. The resulting steam drives a generator as in a conventional power plant. Unlike solar-heating systems, which are installed at the point of energy consumption, CSP plants are typically large, central-station generating facilities.

The other solar-electric technology is photovoltaic cells. Photovoltaic cells are made of a semiconducting material, such as silicon, that releases electrons when struck by light. Cells are typically combined into modules, which in turn are assembled into larger arrays. Arrays can be sized for residential, industrial, or electric-utility use. The most commonly used material is crystalline silicon, but research since the 1970s has produced advances in such newer designs as thin-film cells using noncrystalline (amorphous) silicon, cadmium telluride, and other materials.

Interest in solar energy was stimulated in the 1970s by high oil prices and has been further stimulated by government policies, such as tax credits. Enthusiasm diminished in the 1980s and 1990s as the prices of oil and natural gas fell and many government subsidies lapsed. After the late 1990s interest was renewed by rising energy prices, but the use of solar energy remains limited. In Renewable Energy (2002), the International Energy Agency estimates that in the year 2000, solar heating made up 0.3 percent of world energy consumption and photovoltaic cells contributed less than 0.05 percent.

The major impediment to solar energy is cost. Though solar radiation is abundant and nonpolluting, the equipment required to gather and utilize it is expensive. Solar heating systems have found some commercial adoption in sunny locations for certain applications, especially for heating swimming pools. CSP technologies, though technologically proven, are not yet competitive with other sources of electricity. Perhaps the most promising technology is photovoltaics. By 2002, photovoltaic costs had fallen to about 20 to 30 percent of their 1980 levels. They have become cost-effective in some specialized applications, particularly in remote locations far from existing power lines. From 1992 to 2003, installed photovoltaic capacity worldwide grew by about 30 percent annually.

Economic theory predicts that as exhaustible energy resources are depleted, their prices will tend to rise, making renewable sources more attractive over time. The long-run prospects for solar energy will depend on how its cost compares with other energy sources.

SOLIDARITY
Solidarity, often referred to as social solidarity, is a fundamental concept in the scientific study of human societies, cultures, and social relations. Researchers who were concerned to discover why societies cohere (and why they may disintegrate) hypothesized that social cohesion may be due to ideas or feelings people have about one another. Alternatively, structural conditions, such as a particular arrangement of social roles and relations, might foster conditions producing human unity.

Social theorist Émile Durkheim (1858–1917) first wrote about the problem of social solidarity in The Division of Labor in Society (1893). Durkheim considered society as a moral force characterized by a fundamental duality: Individual consciousnesses comprised the social entity even while society’s norms imposed constraint on any single individual. As societies change, the type of solidarity that “glues” society together also changes. Social solidarity of undifferentiated societies, or mechanical solidarity, is based on likeness (e.g., the cultural similarity of each member of a tribe). Industrial societies cohere because of organic solidarity, based on the interdependency of dissimilar individuals (e.g., occupational diversity due to the division of labor).

Feelings of solidarity are encouraged when individuals strongly identify with a collectivity. Durkheim saw this as one of the bases for religious sentiments. In every religion, boundaries are drawn between the sacred and profane. Through this type of categorization, Durkheim
explains, humans both create a moral ordering for social life and develop the conceptual apparatus necessary for rational thought. “The categories of the understanding” are “born in religion and of religion” (Durkheim [1915] 1965, pp. 21–22). Conceptualizations of time, space, class, causality, and so forth, although linked to brain function, are elaborated and interpreted differently in different cultures. The source of this variation is the social collectivity representing a collective conscience. In Durkheim's view, the collective conscience is expressed through “collective representations,” or symbols. These cultural symbols “are the result of an immense cooperation, which stretches out not only into space but into time as well; to make them, a multitude of minds have combined their ideas and sentiments” ([1915] 1965, p. 29).

Because collective representations express the heritage of an individual as well as provide the intellectual framework for his understandings, the person feels himself linked to a tradition and standards of behavior. Thus, the individual's ideas and feelings stem from a source beyond his personal experience; they come from society itself.

A stable social order rests on the solidarity of its people. What happens when social stability is threatened, through crime, for example? Durkheim argues, somewhat paradoxically, that crime and punishment (the reaction to crime) reinforce the social order. When an infraction is defined as criminal, it places the person who committed the crime outside the social order and deems him worthy of punishment. Those who have not transgressed are affirmed in their status as the law-abiding citizens. Durkheim argues that crime thus builds social solidarity and cohesiveness. Contemporary scholars counter that Durkheim's vision presents an oversocialized conception of humans. For example, Allen Liska and Barbara Warner's (1991) research shows that fear of crime may undermine social solidarity in U.S. neighborhoods where criminal behavior is not checked by authorities. Similarly, Teresa P. R. Caldeirás (2000) research on São Paulo indicates that multiple processes linking crime, poverty, and social status in a context of weak or corrupt policing can lead to increasing social isolation and the fragmentation of public spaces. This, in turn, undermines the potential for democratic development. Liska and Warner's research ultimately supports the Durkheimian position by arguing that the stabilization of crime in certain areas leads to social withdrawal, constraining “opportunities for crime, thereby decreasing both robbery and other crimes” (Liska and Warner 1991, p. 1441). Caldeirás's research, by contrast, challenges the Durkheimian argument by suggesting that “social solidarity” under some repressive conditions is merely an expression of class, caste, or ethnic identification.

If excessive crime and lawlessness indicate the breakdown of society and solidarity, utopian or intentional communities present an idealized vision of a cohesive social order. In Commitment and Community, Rosabeth Moss Kanter identifies a social order of perfect solidarity where society is maintained through individual commitment, not coercion. This is an “imagined utopia,” in which “humankind's deepest yearnings, noblest dreams, and highest aspirations come to fulfillment, where all physical, social, and spiritual forces work together, in harmony, to permit the attainment of everything people find necessary and desirable” (Kanter 1972, p. 1). History abounds with numerous attempts by religious or political idealists to create such societies in miniature. Despite repeated tries, none have found an ideology or set of social arrangements that invariably induces persons to want to do what they have to do: to follow society's rules without question or resistance. In short, there are limits to social solidarity's hold over the individual.

Whereas the ideational approach focuses on symbols, feelings, and identities, a structural approach to social solidarity identifies relational connections among individuals as key for maintaining social order and cohesion. James Moody and Douglas White articulate a social network conception of solidarity that defines structural cohesion formally as “the minimum number of actors who, if removed from a group, would disconnect the group.” Society, in their view, is built up “through the hierarchical nesting of … cohesive [network] structures” (Moody and White 2003, p. 103). The structural perspective is theoretically indebted to Durkheim's argument in The Division of Labor and Georg Simmel's (1858–1918) research on group formation, but methodologically, network analysis draws from graph theory in mathematics. This combination of theoretical and formal traditions allows for greater operational specification of the concept of social solidarity, as well as empirical analysis of how solidarity functions in reality. Using network analytic techniques, researchers are able to determine where, within a social network, relations are most stable and where they are likely to break down. This represents a scientific advance in the field, which is yielding promising results.

Since the nineteenth century, social theorists have viewed solidarity as a key factor underlying the problem of order in society. Durkheim's writings provided a strong impetus for two lines of theorizing: ideational and structural. Sociologists of religion and anthropologists were most interested in Durkheim's arguments about the religious basis of solidarity feelings, concepts, and symbols. Criminologists followed Durkheim in his interest in the social functions of crime. Social network theorists have drawn from Durkheim and others to develop a formal definition of social cohesion, or solidarity, in order to investigate varying social structures. Each line of investigation has increased human knowledge of the internal dynamics and power of social connection.
SOLIDARNOŚĆ

The Independent Self-Governing Trade Union Solidarity (in Polish Niezależny Samorządowy Związek Zawodowy “Solidarność”) is a Polish trade union federation important historically for the role it played as a nonviolent, anti-communist mass social movement in Poland between 1980 and 1989. Solidarity was formed in Gdańsk, Poland, in August 1980 after a nationwide wave of strikes, sparked by price increases imposed by a government facing economic crisis, forced the ruling Communist Party to acknowledge the constitutional right of workers to form free trade unions. As a non-party-sponsored, legally recognized civil organization, Solidarity represented an unprecedented new development in state-society relations in the former Eastern bloc.

Prior to 1980 Poland had been convulsed by several economic and political crises accompanied by widespread social unrest. In each case, however, the party had been able to weather the crisis either by reorganizing its top leadership and introducing new, liberalizing economic and cultural policies (in 1956 and in 1970) and/or by targeting the most outspoken group with harsh reprisals, as occurred in 1968, 1970, and 1976. Signs of a broader, more concerted opposition to the regime came in 1976, with the formation of the Komitet Obrony Robotników (KOR; the Worker’s Defense Committee), a group founded to provide legal and financial support to workers arrested in strikes in Warsaw and Radom of that year. Ranging in composition from former revisionist intellectuals and anti-communist left oppositionists to clergy, KOR became the focal point of a movement to establish links among workers, intelligentsia, and the Church and to form and defend an alternative public sphere outside the bounds of official, state-controlled institutions. If in 1970 striking workers had responded to state violence in kind by setting fire to Gdańsk party headquarters, the new opposition’s strategy was that of peaceful self-organization, signaled by left KOR intellectual Jackie Kuron’s popular motto: “Don’t burn down party committees, found your own!”

By 1980 striking workers were able to draw on a half-decade of experience in one of the most developed underground cultures of opposition in the Eastern bloc. Strikes broke out in Gdańsk’s Lenin Shipyards on August 14, and by August 17 an Inter-Enterprise Strike Committee, formed under the leadership of electrician Lech Wałęsa and including KOR intellectuals in an advisory capacity, had drafted a list of twenty-one demands, many of which extended beyond immediate concerns and addressed fundamental injustices of Communist-Party rule in Poland. The demands called for, among other things, acknowledgment of the right to form free trade unions, for freedom of speech, access to government-controlled media, a halt to reprisals against outspoken critics of the regime, and economic and health care reform. Strikes spread quickly throughout Poland and by August 21, a hitherto recalcitrant government announced its readiness to negotiate. Between August 30 and September 1, state representatives signed a series of agreements recognizing the workers’ right to self-government and obligating the regime to initiate a nationwide debate on the issues presented in the postulates.

The period of Solidarity’s first legal existence (August 1980–December 1981) can be divided into three main stages, as detailed by Timothy Garton Ash in The Polish Revolution: Solidarity (2002, pp. 303–308), David Ost in Solidarity and the Politics of Anti-Politics (1990, pp. 78–79), and Jadwiga Staniszkis in Poland’s Self-Limiting Revolution (1984, pp. 17–28). Initially, propelled by its success in Gdańsk, Solidarity emerged as a powerful social movement, while at the same time containing its opposition within the legal structure of the trade union and refraining from competition with the party for political power. In the second stage, confrontations with the state as well as internal disagreements between reformist and revolutionary factions revealed the inadequacy of this for-
mula. Finally, in its third stage, Solidarity moved into the political arena, openly working for regime change.

Solidarity proved to be too much of a direct challenge to the Communist Party’s monopoly, itself facing pressure from the Soviet Union, and on December 13, 1981, martial law was declared throughout Poland by recently appointed party secretary General Wojciech Jaruzelski. Prominent Solidarity leaders were arrested and interned, strikes and demonstrations were forcefully suppressed by armed riot police, and Solidarity was subsequently delegalized.

The early and mid-1980s saw Solidarity gradually reconstituting itself, now as an underground organization. In 1988 economic crisis forced the party back to the negotiating table with the opposition. This time, with the effects of perestroika being felt throughout the Eastern bloc, politics could be placed squarely on the agenda. Between February and April 1989, in an extraordinary series of negotiations known as the Roundtable Talks, state and Solidarity leaders hammered out an exit from communism for Poland. Free elections were to be held for a portion of seats in parliament, a new senate was to be formed, and a presidency was to replace the role played by the general secretary of the Communist Party. Though the party had insured that key elements of the new government would remain under its control for a transition period, Solidarity won the free portion of the elections by a landslide. With the opening of the Berlin Wall in November 1989, events in Eastern Europe soon outstripped the gradual exit from communist mapped out during the Polish Roundtable Talks, and new, free elections were held in Poland in 1990. Meanwhile, Solidarity, deprived of its opponent, collapsed dramatically as a unified formation, fragmenting into numerous smaller political parties.

The trade union returned to political prominence in 1997 as the animating force behind a coalition of conservative right parties, which won the parliamentary election of that year and governed until 2001.

SOLOW, ROBERT M.
1924–

The American economist and 1987 Nobel laureate Robert Merton Solow was born on August 23, 1924, in Brooklyn, New York. Several years after his birth, economics, in the United States and globally, launched a great leap forward after the stock market crash of 1929 had created the Great Depression that attracted able minds to the study of economics rather than physics or biology. After Solow returned from army service in Europe during World War II (1939–1945), he joined in this movement under the mentorship of the economist Wassily Leontief (1906–1999) at Harvard. Such has been Solow’s originality, wisdom, and energy that his imprint can be found in diverse corners of microeconomics, macroeconomics, and welfare policy.

The awarding to Solow of the Nobel Prize and the American Economic Association’s prestigious John Bates Clark Medal (1961) presumably traces primarily to his seminal 1956 growth model that breathed new life into the earlier pioneering attempts of Paul H. Douglas (1892–1976) to explain statistically the growth of a society’s real output in terms of its historical profiles of labor and of capital inputs. Because both of these time series were so positively correlated in trend, Douglas’s linear-log regressions had been hopelessly ill-conditioned. At Massachusetts Institute of Technology (MIT), where Solow became an assistant professor in 1949 and remained until retiring as institute professor emeritus in 1995, he cut the Gordian knot by introducing into the statistical analysis independent information on market-factor shares. His principal finding was the hypothesis that much of historic gain in outputs was not plausibly connected with “deepening of the Capital/Labor ratio.” Instead, an “exogenous residual” of Schumpeter-like technical innovation shifted upward “total factor productivity” to an important degree. A simplest Cobb-Douglas-Hicks example, à la Solow, would be $Q = (1.03)^t L^{.75} K^{.25}$. It is fitting that Solow as a Harvard student in Schumpeter’s last lectures put the $(1.03)^t$ Schumpeterian parameter of innovation into growth theory, with emphasis upon rate of growth in total-factors productivity.

Fruitful tools of new mathematics—Dantzig linear programming, Kuhn-Tucker nonlinear programming, Bellman stochastic programming—came into wide use among economists after World War II, and Solow’s diverse bibliography illustrates his role as a pioneer. Besides Solow’s depth, his width is exemplified by his many analyses of post-Hotelling exhaustible resources. Besides putting his pen where his heart is, at Resources for the Future (a nonprofit organization focusing on the economic and social dimensions of environmental, energy, and natural
resource issues) and similar organizations, Solow has put his shoulder to the wheels of conservation economics.

President John F. Kennedy’s Council of Economic Advisers—Walter Heller (1915–1987), James Tobin (1918–2002), and Kermit Gordon (1916–1976)—and staff members Kenneth Arrow, Arthur Okun, and Solow set the high water mark for fruitful academic contributions to public policy in the early 1960s. In addition, Solow’s facile pen over the years has reviewed contemporary debates in the public press, and he has expressed criticism of prominent economists, including John Kenneth Galbraith (1908–2006) and Milton Friedman. But his was never an in-your-face attack. Those to the right and the left of Solow generally respected his genial argumentation.

Solow’s colleague at MIT and fellow Nobel laureate Paul Samuelson has dubbed Solow the Enrico Fermi (1901–1954) of economics. Fermi was both a great physicist-theorist and a great physicist-experimentalist; Solow has been both a creator of new theoretical economics and also one who subjected basic economic relations to statistical testing. Without his mathematical doodlings, Solow could not have been one of the wisest in the circle of Tobin, Arrow, and Franco Modigliani (1918–2003). Without his native DNA and mentors (Leontief, Talcott Parsons, Richard Goodwin, Abraham Wald), Solow would not have generated the wisdoms that were uniquely his.

SOLOW RESIDUAL, THE

A growth accounting exercise is used to break down the growth of output into the growth of the factors of production—capital and labor—and the growth of the efficiency in the utilization of these factors. The measure of this efficiency is usually referred to as total factor productivity (TFP). For policy purposes, it may matter whether output growth stems from factor accumulation or from increases in TFP.

The American economist Robert M. Solow set up the grounds for growth accounting in a 1957 article. Solow considered a neoclassical production function,

\[ Y_t = A_t F(K_t, L_t) \]  

(1)

where \( Y_t \) is aggregate output, \( K_t \) is the stock of physical capital, \( L_t \) is the labor force, and \( A_t \) represents TFP, which appears in a Hicks neutral way. After some simple transformations, this equation can be written in terms of the growth rates of these variables. For simplicity, consider a Cobb-Douglas production function \( F(K_t, L_t) = K_t^\alpha L_t^{1-\alpha} \) with \( 0 < \alpha < 1 \). Then, taking natural logarithms and differentiating both sides of (1) with respect to time \( t \), the growth rate of aggregate output can be expressed as,

\[ \gamma_Y = \gamma_A + \alpha \gamma_K + (1-\alpha) \gamma_L \]  

(2)

(For a variable \( E = Y, A, K, L \), the term \( \dot{E} \) stands for the derivative of \( E \) with respect to time \( t \), and so \( \dot{E}/E \) stands for the growth rate.) Note that the growth rates of physical capital and labor are weighted by \( \alpha \) and \( (1-\alpha) \). As is well known, these weights correspond to the respective shares of rental payments for capital and labor in total income. With available data on \( \alpha \) and the growth rates for output, physical capital, and labor, TFP growth can be computed from (2) as the residual. Accordingly, TFP growth is the so-called Solow residual.

Solow carried out this exercise for the U.S. economy for the 1909–1949 period, during which output per man-hour approximately doubled. According to Solow’s estimates, about one-eighth of the increment in labor productivity could be attributed to increased capital per man-hour, and the remaining seven-eighths to the residual. But the residual seemed too large.

To be sure, TFP is shaped by a broad range of influences—a variety of technological, economic, and cultural factors. These factors include innovations in technology, the shift of underemployed labor from agriculture to more productive sectors, economic policies aimed at liberalization and competition, and changes in shopping habits—from tiny shops to department stores. Usually, these changes will increase TFP, although TFP may fall for other reasons, such as trade union restrictions, environmental regulations, and safety measures that limit the use of production factors. (For example, suppose that to conduct weight-lifting exercises a gym requires a spotter; then, two people are needed for a single task, so this rule would decrease TFP.) Other factors that may influence TFP are...
frictions in financial markets, physical and human capital externalities, public expenditures, or any other element that affects the aggregate productivity of the economy.

Measurement is crucial for comprehending the Solow residual. First, observe that aggregate output is roughly the value of market goods and services produced in a society, but for most purposes this measure is too narrow because it leaves out many basic activities that enhance welfare. For instance, from the weight-lifting example we can see that a safety measure will usually decrease output for the benefit of protecting human lives, and it should be clear that the beneficial effects of this rule will not affect output directly. Moreover, output and other aggregate variables may be measured with error; indeed, many Internet activities are not satisfactorily treated in the national accounts. Second, there is the problem of quality adjustment. Various goods and services (e.g., cars, cellular phones) did not exist in the past or are now of much better quality, but these quality improvements are not well recorded in the statistics. Third, there are lags in the processes of innovation, learning, and implementation of technologies. Some current investments will see most of their payoffs far in the future and cannot be evaluated according to today’s productivity. From 1973 to 1989, the United States and some other Western economies experienced a slowdown in TFP growth. Presumably, this productivity slowdown happened because these advanced economies were adjusting to the era of information and communication technologies; in the meantime, productivity—as shown in the statistics—was low.

In spite of these measurement problems, various studies have analyzed the determinants of the Solow residual (Denison 1962; Jorgenson and Griliches 1967) with emphasis on embodied and disembodied technological progress. Advances in technology may be embodied in the latest vintages of capital. Thus, new capital is better than old capital, not just because old capital has suffered wear and tear, but because of the quality improvement that comes with new capital. Therefore, a part of technological progress is embodied in \( K \), and failure to allow for this rise in quality may overstate the growth assigned to TFP. Similar considerations apply to labor: New generations entering the labor force are better educated and by all counts are more productive. In contrast, disembodied technological progress, included in TFP, will be associated with new modes of organization and operation of inputs, as well as other improvements not incorporated into the quality of factors of production. In practice, it has proved difficult to offer reliable estimates for the importance of embodied and disembodied technological progress. Sizable estimates have been reported for the contribution of embodied technological progress in physical capital to growth, but it is puzzling that many cross-country studies (Pritchett 2001) have found that the estimates for human capital to growth are insignificant or do not have the desired sign.

With the availability of broad sets of data in recent years, it has been possible to make cross-country comparisons of Solow residuals. These exercises offer new possibilities to test theories of economic growth. For a broad collection of countries, some studies contend that the growth process can be explained by factor accumulation. For instance, this suggests that the observed high growth rates for output in some fast-growing countries in Southeast Asia may not be long lasting, since there may be decreasing returns in the accumulation of these factors and further investments may become less productive. These studies have been criticized on the grounds of poor measurement of human capital, high physical capital shares, and biased estimates from endogeneity in the variables (Klenow and Rodríguez-Clare 1997; Easterly and Levine 2001). Therefore, the prevailing view is that to a great extent cross-country differences in output levels and growth rates should be attributed to the Solow residual.

In summary, the Solow residual is that part of output growth that cannot be attributed to the accumulation of capital and labor. There is a variety of factors that may contribute to output growth and hence the residual may be sizable. Quantifying the main determinants of the Solow residual may be instrumental in comparisons of growth experiences across countries and in testing theories of economic growth.

SOLZHENITSYN, ALEKSANDR 1918–

Born in southern Russia in 1918, Aleksandr Solzhenitsyn was brought up in highly straitened circumstances. By the time he graduated from Rostov University in 1941 with a degree in mathematics and physics, Solzhenitsyn was an enthusiastic champion of Marxist ideology who hoped to describe anew what he considered the glorious advent of the Russian Revolution. To this end Solzhenitsyn intended to pursue postgraduate literary studies, but the outbreak of hostilities in 1941 led to army service and eventual assignment to a sound-ranging battery on the front lines. In early 1945, Solzhenitsyn was arrested for critical comments on U.S.S.R. leader Joseph Stalin (1879–1953) in letters to a friend (the mail was censored) and sentenced to eight years imprisonment, to be followed by “eternal exile” in a remote area of the Union of Soviet Socialist Republics.

Solzhenitsyn served his sentence in various labor camps and prison research institutes, emerging in 1953 with his Marxist faith shattered and his head full of literary plans. The First Circle, composed mostly in the 1950s (after his exile was annulled), but published only in 1968, reflects his experience in a Moscow prison institute, One Day in the Life of Ivan Denisovich (1962) is based on his incarceration in Central Asia. One Day, Solzhenitsyn’s first publication, appeared in Moscow by special permission of the regime. In early 1945, Solzhenitsyn was arrested for critical comments on U.S.S.R. leader Joseph Stalin (1879–1953) in letters to a friend (the mail was censored) and sentenced to eight years imprisonment, to be followed by “eternal exile” in a remote area of the Union of Soviet Socialist Republics.

In the intervening years Solzhenitsyn gained prominence as a resourceful opponent of the Soviet regime, releasing bitterly critical statements that were distributed by the samizdat network and typically beamed back to the Soviet Union by Radio Liberty. Samizdat literally means “self-publishing house,” an ironic term that refers to a method whereby privately typed materials were distributed chain-letter fashion among opposition-minded individuals who could not get access to the tightly controlled Soviet press. Apart from essays of this type, Solzhenitsyn produced Cancer Ward (1968) and an early version of August 1914 (1971) during this period; both texts were published abroad to the great displeasure of the Soviet regime. In 1970 Solzhenitsyn was awarded the Nobel Prize in Literature, a decision the regime chose to interpret as one more hostile act. The Soviet leadership increasingly viewed Solzhenitsyn as a dangerous political opponent, and an unsuccessful assassination attempt by the KGB was launched in 1971.

The publication of The Gulag Archipelago (1973–1976) had a profound impact throughout the world and moved the regime to arrest Solzhenitsyn in 1974 and expel him from the Soviet Union. After two years in Switzerland, Solzhenitsyn moved to the United States, settling in Cavendish, Vermont, until his return to Russia in 1994. Apart from several high-profile appearances during this period (e.g., the commencement address at Harvard University in 1978), the writer’s time was almost entirely dedicated to a cycle of narratives describing Russia’s slide toward the revolutionary abyss. Entitled The Red Wheel, the cycle comprises ten volumes in the Russian edition (1983–1991) and encompasses the period between the outbreak of World War I in 1914 and April 1917. After his return to Russia, Solzhenitsyn published sketches of his two decades abroad, a number of short stories, essays on literary and political matters, and a two-volume study of the interactions of Russians and Jews in Russian history, Dvesti let vmeste (2001–2002). A thirty-volume Complete Works of Solzhenitsyn’s work was published in 2006.

SOMBART, WERNER 1863–1941

German economist Werner Sombart was born in Ermsleben near the Harz mountains, the son of a prospe-
ous landowner and liberal member of parliament. He studied law, economics, and history at the universities of Pisa, Rome, and Berlin. In 1888 he earned his doctorate in economics from the University of Berlin. After working for two years at the Bremen Chamber of Commerce, he became professor of political economy, first at the University of Breslau and later at the Berlin Business School. In 1918 he was appointed full professor at the University of Berlin.

Over his entire career Sombart tried to explain the origins and growth of the capitalist system of economic organization. In addition to his multivolume work on modern capitalism, he published four specialized books on the emergence of capitalism, relating it to such diverse factors as the bourgeois mentality, the Jewish people, warfare, and luxury consumption. To ground his theories Sombart employed a massive quantity of secondary historical material, varying from statistics and letters to novels and travel accounts. Because of his historical approach to economic issues, he is often seen as the last member of the German historical school to dominate economic thinking in Germany in the second half of the nineteenth century. It is difficult, however, to place Sombart in any school of thought, because his theories and political views changed repeatedly. He started his career as a Marxist economist, became a conservative, and ended as a sympathizer with Adolph Hitler’s Nazi regime.

Undoubtedly, Sombart’s masterpiece is Der Moderne Kapitalismus (Modern Capitalism), published in 1902, expanded in 1916–1917, and enlarged in 1927. This three-volume work, which has never been translated into English, explored the historical evolution of the European economy in the direction of modern capitalism. It was Sombart, not Karl Marx, who coined the word capitalism and described it as a unique economic system in human history characterized by the passion of entrepreneurs to build up pecuniary capital—in other words, to make money. He divided the capitalist era into three stages: (1) early capitalism (1500–1760), dominated by a handicraft mentality, (2) high capitalism (1760–1914), in which the Industrial Revolution spread from England to western Europe and the United States, and (3) late capitalism (starting with World War I), typified by growing state intervention. Next to the entrepreneurial pursuit of profit, Sombart identified major historical events such as the discovery of double-entry bookkeeping and the application of new technologies in industry as the main drivers of capitalist development. With its richness of facts and speculative notions, the book is “highly stimulating even in its errors,” as renown economist Joseph Schumpeter (1883–1950) aptly put it.

One of the studies Sombart published in connection with Der Moderne Kapitalismus was Die Juden und das Wirtschaftsleben (1911), translated as The Jews and Modern Capitalism (1951). Unlike the well-known sociologist Max Weber (1864–1920), who linked the rise of capitalism to the Protestant work ethic, Sombart suggested a link between the Jews and capitalist development. As he saw it, the shift in entrepreneurial activity from southern to northern Europe between the fifteenth and seventeenth centuries resulted from the move of Jews from Spain, Portugal, and Italy to Germany, Holland, and England. For Sombart, it was no surprise that areas from which the Jews fled underwent economic decline, whereas those they entered gained strength; as he saw it, the Jewish character and religion had “the same leading ideas as capitalism” (1951, p. 205). Sombart’s book did not express outright anti-Semitism; but his discussion of Jews as a group was rife with prejudices that clearly laid the ground for his later sympathy with the Nazis.

Although Sombart was the most productive German economist of his time, he did not achieve fame or earn widespread admiration. His work is overly descriptive, disproportionately concerned with history, sloppy with data, and lacking in theoretical rigor; moreover, his political positions were unsavory. Still, Sombart’s historical approach to economic development influenced the first American institutional economists, the French historians of the Annales school, and, most importantly, the economist Schumpeter. For example, Sombart coined the popular term creative destruction, which, along with some of his insights on capitalism, is usually attributed to Schumpeter. Since the late 1990s there has been some renewed interest in Sombart’s work, owing to the growing emphasis on the role of historical specificity in economics.

Gert-Jan Hospers
SOROS, GEORGE
1930–

George Soros, Hungarian-born American financier and philanthropist, is the second son of Tivadar and Erzebet Soros. He was thirteen years old when Nazi Germany invaded Hungary. To escape the German genocide of the Jews, the Soros family survived the occupation in secret hideouts under fake identities. In 1946 George Soros immigrated to England from the Russian-controlled country and attended the London School of Economics.

After graduation, Soros managed to break into the nepotistic merchant banking industry in London, where he was hired to be a trainee by a Hungarian managing director at Singer and Friedlander. In 1956 he was hired by another trainee’s father to work in international arbitrage at his small brokerage firm in New York. In the European investment boom following the formation of the Coal and Steel Community, Soros made a name for himself as an analyst in European securities at Wertheim and Company and later at Arnold and S. Bleichroeder.

SOROS THE FINANCIER

In 1966 Soros started managing a $100,000 model portfolio of American securities for Arnold and S. Bleichroeder, which was later turned into an investment fund and, in 1969, a hedge fund. In 1973 Soros left the firm to start his own hedge fund, which evolved into the Quantum Fund. Assets under his management reportedly returned 3,365 percent from 1969 to 1980, compared to 47 percent for the Standard and Poor’s stock index. The spectacular investment success caught public attention in 1981, when Soros was billed by Institutional Investor as “the world’s greatest money manager.” Unfortunately 1981 became the first year that he lost money. He subsequently left daily management of the fund to outside managers and later an internal staff, satisfied to be the owner and coach.

Soros is probably best known as “the man who broke the Bank of England.” His fund bet heavily on the devaluation of the British pound in the fall of 1992 and made over $1 billion from the bet and other related derivatives transactions. The ensuing infamy left Soros undisturbed as he saw the devaluation as something bound to happen and insisted he operated within the rules. He is also widely believed to have been a force behind the currency speculations during the Asian financial crisis in 1997, an accusation he denied. The former Malaysian prime minister Mahatir Mohamad, one of Soros’s fervent critics at the time, said in 2006 that he now believed Soros had not been involved.

SOROS THE PHILANTHROPIST AND PHILOSOPHER

Soros’s philanthropic activities, which started long before his rise to fame, have centered around his pursuit of open societies. He has written extensively on the subject, which resonated deeply with his teenage experience. He believes that the markets are always wrong and that he himself is just as fallible. Society is inundated with similar fallibilities. He believes that, under an open society where free expression is cherished and differences in opinions are allowed, people are best equipped to keep their own biases to the minimum.

Soros believes the United States has justifiably pursued an open market policy thanks to its economic and political might. Developed legal systems, a business-friendly economic environment, and possession of the world’s main trading currency have attracted capital to the United States. The negative effects on certain domestic industries have been limited by trade restrictions posed by the World Trade Organization.

Soon after he earned his first $25 million, Soros started giving his wealth away to promote the principles of open society. In 1979 he provided scholarships to black students at Cape Town University. South Africa’s racial segregation policies at the time made it a prominent closed society. Soros thought the university championed open society by treating black students equally. He withdrew support eventually after he found out that scholarships were not all used to fund additional black students as he intended.

In 1984 Soros created the Soros Foundation in Hungary to provide financial support for scholars on a competitive basis. By 2006 the network had expanded to thirty-two foundations spanning eastern Europe, Africa, and Central America. The most profound impact has been in eastern Europe, where Soros funded scholarships for academics to study abroad and supported libraries and health education programs. Although each foundation developed its own program according to its specific needs, all operated under the expectation that they would be prototypes of open society. In 1991 Soros set up and financed the Central European University, with campuses in the early twenty-first century in Budapest, Prague, and Warsaw, to train graduate students in various subjects of the humanities in the hope that they would promote the practice of open society.

The South became a discrete region by an extended process linked to African American slavery. Slaves worked in all the American colonies, but especially on plantations growing tobacco in Virginia and rice in South Carolina. By the time of the first federal census in 1790, slaves comprised 31 percent of the U.S. population south of Pennsylvania, but less than 2 percent elsewhere. With the invention of the cotton gin in 1793, cultivation of the fiber expanded widely south of Virginia, spreading slavery and the plantation system across the southern interior and gradually tying the South together as the “Cotton Kingdom.”

Representatives of the free and slave states clashed in the Constitutional Convention of 1787, but regional self-consciousness did not spread widely until after 1820, as southern whites reacted to a growing abolition movement in the North and to northern opposition to slavery’s expansion. In 1860 a northern majority elected an avowedly antislavery president, Abraham Lincoln (1809–1865), prompting eleven slave states to leave the Union and form the Confederacy. Southern defeat in the ensuing Civil War brought the abolition of slavery, first by the Emancipation Proclamation (1863) and more fully by the Thirteenth Amendment to the U.S. Constitution (1865).

During Reconstruction (1865–1877), native southern whites used violence and intimidation to regain power over their state governments and the ex-slaves. The plantation system continued under tenancy arrangements that left blacks and many whites largely impoverished and uneducated. Beginning in the 1890s, white Democrats used poll taxes and literacy tests to strip most black men of the right to vote, followed by laws requiring the strict segregation of the races in all public facilities. In response, millions of black southerners fled to find better opportunities in the North and West. Until the civil rights movement of the 1950s and 1960s brought new federal legislation, widespread poverty, legal segregation, black disfranchisement, and exclusive control by an all-white Democratic Party characterized the so-called Solid South. Before these reforms, unique social and political institutions—and the prolonged struggle to maintain them—made the South unmistakably different from the rest of the United States, and fed a strong regional identity, especially among whites.

Despite these dominant regional patterns, diverse regional subcultures have long flourished in the South. The Appalachians and similar patches of hill country did not define the entire region. Eleven states seceded to form the Confederate States of America in 1861: Virginia, North Carolina, South Carolina, Georgia, Florida, Tennessee, Alabama, Mississippi, Louisiana, Arkansas, and Texas. Four other slave states did not secede: Delaware, Maryland, Kentucky, and Missouri. The modern state of West Virginia broke away from Virginia during the Civil War, creating lasting disagreement over whether it should be considered southern. The U.S. Census defines the South as the former slave states (minus Missouri), plus Oklahoma and the District of Columbia. Accepting the reality that state lines have never circum-

SEE North and South, The (Global).

**SOUTH, THE (USA)**

Historically and culturally, the South is the most distinctive region of the United States. Once a center for African American slavery, the South is the only U.S. region to have fought for a separate national existence. Following defeat in the Civil War (1861–1865), poverty and legalized racial discrimination marked the southern states until the last decades of the twentieth century. While slavery and racial strife never dominated all parts of the South, they contributed to the economic, political, social, and cultural isolation of the entire region. As a result, W. J. Cash expressed a broad consensus when he called the South “not quite a nation within a nation, but the next thing to it” (1941, p. xlviii).

Like many other world regions, the South has no precise definition. It includes a variety of climates and geographical features, ranging from subtropical coastal swamps to the Appalachian Mountains, which include the highest peaks east of the Mississippi River. The border between Pennsylvania and Maryland (the Mason-Dixon Line) divides North from South traditionally, but does not define the entire region. Eleven states seceded to form the Confederate States of America in 1861: Virginia, North Carolina, South Carolina, Georgia, Florida, Tennessee, Alabama, Mississippi, Louisiana, Arkansas, and Texas. Four other slave states did not secede: Delaware, Maryland, Kentucky, and Missouri. The modern state of West Virginia broke away from Virginia during the Civil War, creating lasting disagreement over whether it should be considered southern. The U.S. Census defines the South as the former slave states (minus Missouri), plus Oklahoma and the District of Columbia. Accepting the reality that state lines have never circum-

---

Shi Larry Cao
not support plantations, but sustained a distinct white folk culture that became the seedbed of modern country-and-western music. Equally distinct African American cultures developed in the largely black plantation districts. African cultural survivals, including the unique Gullah language, marked the Sea Islands of South Carolina and Georgia, while other black communities developed special musical traditions, especially New Orleans jazz and the Mississippi Delta blues. Lying between the mountains and the coastal lowlands, the Piedmont South fostered industrial development with urban centers like Atlanta and Charlotte.

Isolation and distinctiveness have encouraged southern stereotypes. Racial prejudice and exploitation encouraged images of both black inferiority and universal white racism. Violence, ignorance, and laziness have been attributed to southern whites and blacks alike. Plantation owners have been credited with aristocratic gentility, and poor whites scorned for hopeless degradation. The roots of these stereotypes are slowly giving way, but popular images only die gradually.

The South has changed rapidly since the end of World War II (1939–1945). Vigorous industrial recruitment, often founded on low wages, weak regulations, and hostility to labor unions, attracted outside industry and led to massive urban and suburban growth. The civil rights movement ended legalized segregation and stimulated a two-party political system, as millions of new black voters entered the Democratic Party while many whites switched to the resurgent Republicans. Southerners of both parties acquired leading roles in national politics, as Democrats won presidential elections with Jimmy Carter (1976) and Bill Clinton (1992 and 1996) and came close with Al Gore (2000), while southern Republicans like Newt Gingrich, Trent Lott, and Jesse Helms exercised a powerful conservative influence on Congress from the 1990s onward. Black migration reversed direction, lifting the region's black population by 7.2 million between 1970 and 2000. Prosperity attracted millions of other newcomers as well, including northern-born whites and Hispanic immigrants, but the offshore flight of low-wage manufacturing has distressed many southern industrial communities.

Recent changes have led some observers to worry that the South may disappear as a distinct region, but change has come on top of deep-seated historical experiences that are likely to give distinct characteristics to southern development for a long time to come.

SOUTH SEA BUBBLE

The South Sea Bubble was one of the first famous financial bubbles of modern times. The shares of the South Sea Company rose rapidly to ten times their par value within a few months in 1720, and even more swiftly fell back. These rapid fluctuations arose in the process of creating the first modern fiscal state. It was difficult to manage higher taxes and borrowing, and a bubble was the result.

The Glorious Revolution of 1688 brought King William (1650–1702) from the Low Countries to the English throne, together with his military ambitions and Dutch financial bureaucrats to help finance the resulting wars. The English government dramatically increased its taxes, creating a tax basis that assured investors that the government's bonds could and would be paid.

The English government then tried to figure out how to extend its borrowing. It issued a variety of securities that were not easily transferable; some were irredeemable. While the government's cost of servicing the national debt was substantial, most annuities traded at large discounts. Imitating the French model of John Law (1671–1729), the South Sea Company (which never traded in the South Seas) offered to exchange existing government debt for equity in the company that could be traded easily. The South Sea Company would buy and hold government debt, paying dividends on its stock from the interest it received on the bonds, and profiting by providing liquidity to holders of government debt. The company's first major venture was the debt conversion of 1719 in which it exchanged £1 million for newly issued stock. The government's debt payments fell, former debt holders saw the
The value of their securities rise, and the company earned a considerable profit.

The South Sea Company then proposed to exchange about £30 million of the national debt for its own shares, paying the English Treasury for the privilege. Parliament and the king approved the conversion by early April 1720, by which time the stock had more than doubled from January. The company obtained the right to issue new shares to finance the conversion, but the conversion ratio was not fixed, and the company could obtain government debt more cheaply as its share price rose. Public interest and company activities drove the price ever higher. Many investors bought South Sea shares knowing that they were overpriced; they hoped to sell the shares for even higher prices before the shares returned to a more reasonable level. The company issued fresh equity in four subscriptions, at higher and higher prices. It also lent generously against its own shares, reducing their supply and increasing demand for them.

The price of South Sea stock rose from around £140 in January 1720 to £300 at the start of April and £800 at the start of June. The price was near £1,000 in the summer, but it fell precipitously in September, back to £200 by October. The rapid fall of share prices in September 1720 probably was brought about by some small event that made it clear to many traders that buying opportunities based on expected price rises were coming to an end. The bubble collapsed, taking the prices of other stocks in London and Amsterdam down with the South Sea Company. The problem of providing liquid government debt was not solved until the introduction of consols (consolidated English government debt with no due date) a generation later.

SOUTHERN BLOC

The term southern bloc refers to a coalition of southern Democratic representatives and senators who united with Republicans to advance shared legislative interests, principally to prevent federal involvement in race relations in the U.S. South. The seniority of many southern bloc members enhanced their legislative influence because they held so many congressional committee chairmanships. The “southern bloc” had political connections to the “southern strategy” in presidential politics that emerged in the 1960s.

The southern bloc was another instance of the sectionalism that had always unified southerners in both houses of Congress. From the beginning of the nation, southern interests had voted together regarding issues of slavery. Beginning in the 1930s in an effort to stop Franklin D. Roosevelt’s plan to “pack” the Supreme Court, southern Democrats voted with Republicans against nonsouthern Democrats. The alliance of southern Democrats and Republicans formed a “conservative coalition.” The southern bloc and the farm bloc also shared interests, for as V. O. Key Jr. noted about Congress in the 1940s: “Between the extreme of urban industrialism and of prosperous, rural Republicanism, the poor, southern Democracy occupies a position in the political center” (1949, p. 378). Recent instances of the southern sectionalism that shaped the southern bloc include the occasion during the Reagan years when several southern House Democrats (“boll weevils”) joined with Republicans to enact the president’s budget. In 1993 southern Democrats and Republicans coalesced to pass the North American Free Trade Agreement.

Southern U.S. senators, given the Senate rules allowing filibusters (unlimited debate), have played a critical role in the work of the southern bloc. Tom T. Connally of Texas (1877–1963) was among the first leaders of the bloc in the Senate, and Richard B. Russell Jr. of Georgia (1897–1971) led the Senate’s southern bloc between 1945 and 1969. Before the 1960s, virtually all southern senators were members of the bloc. Some did not formally ally themselves with it: Lyndon B. Johnson of Texas, Estes Kefauver of Tennessee, and Ralph W. Yarborough of Texas. The Declaration of Constitutional Principles (March 12, 1956)—the so-called “southern manifesto” — which assailed the Supreme Court’s Brown v. Board of Education decision (1954 and 1955) was signed by nineteen of the twenty-two southern senators (not signing were Kefauver, Johnson, and Albert A. Gore Sr. of Tennessee) and by 82 of the 106 southern House members.

Southern senators did not have majority support for voting against federal intervention in race relations. As a minority, the bloc resorted to delaying tactics allowed by the Senate rules in order to prevent passage of important civil rights legislation. Filibusters by the southern bloc that succeeded included those against anti-lynching bills in 1935 and 1938; anti–poll tax measures in 1942, 1944, and 1946; fair-employment practices legislation in 1946; and voting rights bills in 1960. In 1957, having significantly watered down a civil rights bill, the southern bloc
did not filibuster it. But one of its members, then-Democrat Strom Thurmond of South Carolina, filibustered the bill for more than twenty-four hours.

Between 1938 and 1963 the southern bloc, allying with some western Democrats and Republicans beat back all eleven attempts to end filibusters on civil rights legislation. Such attempts seek to invoke cloture, a procedure to end debate and vote on the measure being discussed. From its enactment in 1917 to its amendment in 1975, Senate Rule XXII required a vote by two-thirds of the Senate to end debate; in 1975 that proportion was reduced to three-fifths, so that sixty senators could halt a filibuster. On June 10, 1964, after a filibuster lasting seventy-four days, the longest filibuster in history, the Senate successfully imposed cloture for the first time on a civil rights bill. The Senate also invoked cloture on filibusters against civil rights bills in 1965 (voting rights) and 1968 (open housing).

In presidential politics, a “southern strategy” sought to unite the white South and Republicans to mutual advantage. “Southern strategy” was a pejorative phrase charging Republicans with racist or at least political intentions to court southern white support by taking more pleasing positions on desegregation. In 1964 the Republican presidential nominee Barry Goldwater (1909–1998), who had voted against the 1964 Civil Rights Act, carried the five Deep South states with a hard-edged southern strategy, but lost in a landslide to Democratic nominee Lyndon Johnson. In 1968 the Republican nominee, Richard Nixon, employed a softer southern strategy to curb the threat posed by the American Independent Party candidate George C. Wallace (1919–1998). Senator Thurmond, who had run as the States’ Rights Democratic Party (Dixiecrat) presidential candidate in 1948 and switched to the Republican Party in 1964, was a key ally in this strategy. Thurmond battled Wallace, claiming a vote for Wallace was essentially a vote for the Democratic candidate, Hubert Humphrey (1911–1978). The winner, Nixon, carried South Carolina and four other southern states not in the Deep South.

In the 2000 and 2004 presidential campaigns, with southern whites identifying more with the Republican Party, the Republican nominee, George W. Bush, abandoned the southern strategy of previous Republican presidential candidates to seek greater black and Hispanic support, and he did make some headway among Hispanic voters, but not among black voters.

Since the 1960s the political bases that supported the southern bloc have been changed by the growing black vote in the South, which is increasingly critical to the election of Democrats; by Republican gains in the former solidly Democratic South; and by the social and economic convergence of the South with the non-South. Conservative southern Democrats have largely vanished as conservative southern voters now ally more with Republicans. In the 1980s and later, civil rights measures received considerable support from southern Democrats, and the conservative coalition appeared less frequently in congressional voting. Indeed, Congressional Quarterly discontinued its annual report on conservative coalition voting after the 1998 session of Congress, in which the conservative coalition appeared on only 6 percent of the roll call votes.

SOUTHERN STRATEGY
In American politics, the “southern strategy” refers to efforts by the Republican Party and its candidates to win presidential elections since 1964 by appealing to conservative whites (especially white southerners) disaffected with the Democratic Party by its strong embrace of civil rights laws in the 1960s and its racially egalitarian policies since.

BEFORE 1960: THE UNSTABLE DEMOCRATIC PARTY COALITION
While racial discrimination existed nationwide before 1960, it was especially pervasive and severe in the South. Region-wide, but especially in the Deep South (Louisiana, Mississippi, Alabama, Georgia, and South Carolina), the politically and economically dominant white population enforced segregated schools, neighborhoods, and public establishments, severe discrimination in jobs and housing, and denial of voting rights for blacks. Virtually all southern Democratic politicians favored racial segregation and antiblack discrimination; candidates that did not were unelectable. Meanwhile, most white southerners vilified
Republicans as the party of the Union cause during the Civil War and of the hated Reconstruction era, when federal troops occupied southern states after the war. From 1932 into the 1940s, the Democratic Party’s majority coalition nationwide was owed in part to intense Democratic loyalties among most white southerners.

Such support remained strong as long as Democrats did not push aggressively for civil rights for blacks. But in 1948 Democratic Party convention delegates supported this plank in the party platform: “The Democratic Party commits itself to continuing efforts to eradicate all racial, religious, and economic discrimination.” In vehement opposition, delegate Strom Thurmond, then governor of South Carolina, stalked out of the convention, leading other Deep South delegates in tow (Edsall and Edsall 1991, p. 34). The dissidents formed the States’ Rights Democratic (“Dixiecrat”) Party, with Thurmond as their presidential candidate. The Dixiecrats carried several southern states in 1948, serving early notice to the national Democratic Party that aggressive action on civil rights would result in the party losing much white southern support. In 1954 Thurmond won a U.S. Senate seat from his native South Carolina; in 1964, he switched to the Republican Party.

1960 TO 1964: RACIAL ISSUES REEMERGE, AND REPUBLICANS MOVE TO THE RIGHT

During the 1950s events such as the Supreme Court’s 1954 ruling ordering schools to desegregate (Brown v. Board of Education) and the 1957 crisis attending the integration of Central High School in Little Rock, Arkansas, kept civil rights issues on the national agenda. However, the Democratic and Republican parties equivocated on civil rights issues, until 1964. That year, President Lyndon B. Johnson and northern members of Congress from both parties overcame fierce southern Democratic opposition to pass the Civil Rights Act of 1964, which outlawed segregated public places, including most private businesses, and banned employment discrimination. Meanwhile, Republicans moved sharply rightward on racial issues (Carmines and Stimson 1989), nominating Arizona senator Barry Goldwater for the presidency in 1964. Far more conservative on racial issues than previous Republican candidates had been, Goldwater argued forcefully against the Civil Rights Act, emphasizing his view that proper jurisdiction over civil rights policy lay with the states, not the federal government. Goldwater’s argument was not openly racist: He neither vilified blacks nor made openly segregationist appeals, as Thurmond and other southern Democratic politicians had for decades. Nonetheless, Goldwater’s position was enormously attractive to white southerners enraged by the national Democratic Party’s embrace of civil rights laws. President Johnson won a landslide reelection over Goldwater in 1964. But Goldwater carried five Deep South states that had not voted Republican in presidential elections since Reconstruction. The Democratic lock on the South was broken, and issues and developments after 1964 would continue to erode white southerners’ loyalty toward the Democratic Party.

The southern strategy, then, first emerged in 1964 to attract white southerners by positioning the Republican Party as the new political home for racial conservatism (Carmines and Stimson 1989). Columnist Robert Novak (1965) described the southern strategy as encompassing staunch anti-Communism in foreign affairs and conservative appeals for a less activist federal government in domestic affairs, and deemphasizing civil rights without endorsing racial segregation or discrimination, to attract white southerners but avoid alienating moderate whites with raw racial appeals. After 1964 the southern strategy flowered, but with a changing issue focus, favoring more covertly racial issues such as social welfare programs, “law and order,” school busing, and, in the 1980s, affirmative action and violent crime.

1965 TO 1972: YEARS OF TURMOIL AND NIXON’S SOUTHERN STRATEGY

By 1968 Republicans were refining their 1964 appeals and discourse and extending them to new issues. In 1965 President Johnson signed the Voting Rights Act of 1965, throwing the federal government’s full weight into guaranteeing voting rights for southern blacks. The next three years were tumultuous, seeing the rise of black militant groups and major riots in Los Angeles (1965), Detroit (1967), and many other cities in 1966 and following the assassination of Martin Luther King Jr. in 1968. After another assassination—that of Democratic presidential candidate Robert Kennedy—the 1968 Democratic National Convention met in Chicago. Chaotic scenes of police beating demonstrators in Chicago’s streets and parks echoed the tumult within the convention hall, as the party’s delegates splintered over the issue of continuing the Vietnam War. Republicans sought to capitalize on the turbulence of the late 1960s by calling for “law and order.” This appeal resonated strongly with conservative whites nationally, but especially white southerners. By 1965 almost all American homes had televisions, and televised footage of urban riots, assassinations, antiwar protests, black militant groups, recreational drug use and sexual activity among young people, and unrest at the Democratic Party convention fostered perceptions that under Democratic governance the nation and the social fabric were unraveling at the seams.
Guided by former Thurmond political advisor Harry Dent, the 1968 Republican nominee, Richard Nixon, sent unmistakable signals of sympathy to white southerners. Meeting with southern Republican delegates, Nixon supported limiting federal government intrusion into their region’s affairs. He assured them his administration would not “ram anything down your throats,” said he opposed school busing, promised to appoint “strict constructionists” to the Supreme Court, and opposed federal intervention in local school affairs (Carmines and Stimson 1989, p. 53). Nixon’s candidacy was complicated by the American Independent Party candidacy of former Alabama governor George Wallace, who also appealed to white southerners with a populist, antigovernment, “law and order” campaign. Although Wallace carried several southern states, Nixon eked out a win in a divided nation exhausted by war in Vietnam and rocked by protests, assassinations and violence, and racial unrest at home.

1969 AND LATER: THE SOUTHERN STRATEGY EVOLVES, BUT CONTINUES

During the Nixon presidency directly racial issues, such as school busing, and covertly racial issues, such as social welfare spending, assumed center stage. Controversies over school busing arose owing to court rulings such as the 1971 *Swann v. Charlotte-Mecklenburg* decision requiring busing to achieve racial integration. Nixon won a landslide reelection in 1972, winning every southern state. Later Republican candidates continued to make covert racial appeals toward conservative whites nationwide, but especially conservative southern whites. Ronald Reagan launched his 1980 campaign with a speech emphasizing “states’ rights” in Philadelphia, Mississippi, where the kidnapping and murder of three civil rights workers had shocked and galvanized the nation in 1964. Reagan also made racially charged remarks about “welfare queens” in stump speeches, tried to dismantle the U.S. Civil Rights Commission, opposed affirmative action programs, and advocated cutting federal aid to cities and social programs that especially benefited blacks.

In 1988 George H.W. Bush’s campaign portrayed Democratic candidate Michael Dukakis as “soft” on violent crime in a racially charged campaign designed by Republican advisors including Lee Atwater, a native South Carolinian, protégé of Harry Dent, and former campaign director for Republican U.S. Senator (and 1948 Dixiecrat presidential candidate) Thurmond. The campaign featured the story of William “Willie” Horton, a black convict who, released from prison on a weekend furlough (a controversial program supported by Massachusetts governor Dukakis), escaped to Maryland, where he attacked a couple in their home. Republican strategists openly exploited the Horton case, with one TV ad showing a sinister and unruly-looking Horton in police custody. Political scientists Donald Kinder and Lynn Sanders (1996) and Tali Mendelberg (2001) demonstrate that the effect (if not the intent) of the Horton campaign was to stoke white fears of black violence and criminality for political gain. Atwater promised that “by the time this election is over, Willie Horton will be a household name.” Later, he said “the Horton case is one of those gut issues that are value issues, particularly in the South, and if we hammer at these over and over, we are going to win.”

In the four presidential elections between 1992 and 2004 racial issues have receded in importance, and moral and religious issues have become more prominent. These developments have fueled continued Republican realignment among white southerners, but generally for reasons remotely related to race. As the first southern conservative president since Andrew Jackson (Lind 2003), George W. Bush has enjoyed very high approval ratings from white southerners. Bush’s social conservatism and eager use of force overseas since the September 11, 2001, attacks resonate strongly with the militarism (Nisbett and Cohen 1996) and social and religious conservatism (Smith 1997; Green et al. 2003) common among white southerners. For Democrats, the region is now forbidding territory. In the seven presidential elections since 1980, Republican candidates have swept every southern state four times (1984, 1988, 2000, and 2004), and won all but one southern state, Georgia, in 1980. In 1992 and 1996 Arkansas native Bill Clinton carried some southern states, but most southern electoral votes still went to the Republicans.

The southern strategy, launched in 1964 and refined with a panoply of racially charged issues from 1968 to 1988 and other, generally less race-related, issues since 1992, has borne fruit for Republicans. Most white southerners are now reliably Republican in voting for president, and increasingly in voting for Congress and state offices as well. Meanwhile, as reported by Mike Allen in the *Washington Post* (2005), Republican National Committee chairman Ken Mehlman tacitly admitted the racial basis of the southern strategy. In prepared remarks to the National Association for the Advancement of Colored People, Mehlman acknowledged that “some Republicans [were] trying to benefit politically from racial polarization,” adding that “we were wrong” and calling it “not healthy for the country for the political parties to be so racially polarized.”

Still, southern Republicans may be continuing efforts to polarize the party system by race. The Republican-led 2003 redistricting in Texas has nearly eliminated white Democrats in Texas’s U.S. House of Representatives delegation. After the 2004 election, Texas’s U.S. House delegation had eleven Democrats—one white and ten black or
Latinos—and twenty-one Republicans—one Latino and twenty white. Similarly, in 2005 Georgia Republicans passed a controversial “Voter ID” law requiring would-be voters to show a driver’s license or other state-issued photo identification. Georgia’s black lawmakers walked out of the statehouse in angry protest over the law’s passage. Civil rights groups charged the law would disproportionately suppress black voting, since blacks are less likely to own cars and thus have drivers’ licenses. The law required those without drivers’ licenses to purchase a state-issued identification card, but at offices that were scarce in heavily-black Atlanta. An injunction, passed later in the year, blocked the law from further being enforced.

SOVEREIGNTY
Political scientists trace the conventional definition of sovereignty—supreme legal authority exercised over a particular territory and people—to the writings of European legal and political philosophers from the sixteenth to nineteenth centuries. Many view sovereignty as a defining feature of political modernity, and some critical and postmodern theorists regard sovereignty as a discursive practice and, as such, a central problem for contemporary politics, particularly world politics. It is argued that the discursive practice of sovereignty constructs and sustains the state as the supreme authority in a world in which human well being and social justice would be better served by finding ways of simultaneously holding states more accountable to people and by enlarging the role of global civil society. By some accounts, the sovereign state is the cause of war and international anarchy as well as the primary obstacle to the construction of a humane world order.

Writings on sovereignty over the past four centuries reflect two distinct views, one unlimited and absolute, the other restrictive and conditional. The works of Niccolò Machiavelli (1469–1527), Jean Bodin (1530–1596), Thomas Hobbes (1588–1679), and John Austin (1790–1859) fall into the first category. In Austin’s view law is “the command of the sovereign.” Machiavelli and Hobbes held that the recognition and exercise of sovereignty as supreme authority is necessary to the establishment of effective government. Bodin’s conception was so absolute that, in his view, elected officials could not be said to hold sovereign power at all. Such absolute sovereignty was mitigated when it passed historically from the “divine right of kings” in the sixteenth through the eighteenth centuries to the state or government. Though Hobbes and Austin did not deny a role for the people, their emphasis on the state as the locus of sovereignty is evident today, as there are no requirements that states be democratic in order to be recognized as possessing sovereign authority accountable to no higher authority, hence the criticism of state sovereignty by today’s human rights advocates. In contrast, John Locke (1632–1704) and Jean-Jacques Rousseau (1712–1778) argued for a shift in the locus of sovereignty from government to people.

Recent criticisms of sovereignty as a discursive practice stem largely from the work of the influential postmodernist Michel Foucault (1926–1984), who sought to unveil how sovereignty discourses both correspond to and constrain the way power is constituted in social relations in specific historical and cultural contexts. This exercise reveals the paradox of modernity, where sovereignty, said to reside within the individual, has a totalizing effect when exercised by the state. Philosopher Jacques Derrida (1930–2004) also notes the contradiction between, on the one hand, sovereignty understood as one group or individual exercising a superior power over others and, on the other, modernity’s promise of democracy and equality.
Sovereignty can be viewed within particular contexts such as international law, international political relations, or through a network of legal relations within a federal state, such as the United States. In international law, an absolute concept of sovereignty is less relevant than the "sovereign equality" of states. States freely enter into legally binding agreements through treaties, but in doing so, they in effect agree to a diminishment of sovereignty. An example is the optional clause to the Statute of the International Court of Justice, which imposes compulsory jurisdiction on all states signing the clause. Some argue that the members of the European Union give up some state sovereignty in favor of "pooled" sovereignty. A distinction is also made between de jure sovereignty, that is, the legal status of sovereignty, and de facto sovereignty, which allows a state to act sovereign as a practical matter even if not supported by de jure, or legal, recognition.

Sovereign equality is a legal attribute of states in their legal and political relations with another. New states "come into existence" as a result of being recognized by existing states. Thus the success of a people or a secessionist movement in seeking recognition as a sovereign state will ultimately depend on the political will of existing states. States may also experience diminished sovereignty as a consequence of violating international norms or as a result of the enforcement of international law by other states. Following their defeat in World War II (1939–1945), for instance, Germany and Japan formed postwar governments under the supervision of the international community, and their ability to maintain military forces was curtailed as a condition of their defeat. More recently, following the United Nations Security Council enforcement action in 1991, Iraq's sovereignty was diminished by the International Atomic Energy Commission inspections and the U.N. designation of "no-fly zones."

In a federal system such as the United States, sovereignty can be reserved or shared between the federal and state or provincial governments. Additionally, indigenous peoples within a state can exercise or assert indigenous sovereignty. Although the term indigenous has gained widespread use internationally, U.S. law refers to "tribal sovereignty," while Canada and other settler states refer to "aboriginal" sovereignty. The history of tribal sovereignty in the United States has been troubled, uneven, and often inconsistent, in large part because U.S. law asserts congressional "plenary power" over indigenous peoples. U.S. law treats tribal sovereignty as a lesser or subordinate form of sovereignty. Though eroded through many of the court decisions during most of the twentieth century, in the later twentieth and early twenty-first centuries the right of self-determination has been strengthened as U.S. law recognizes that indigenous tribes and nations possess many attributes of sovereignty. A move toward international recognition of indigenous rights may further strengthen the legal and political basis of indigenous sovereignty, which indigenous peoples often regard as the ability to control one's own political destiny.

Sovereignty has no intrinsic moral authority. As a legal doctrine or norm, sovereignty is said to have settled the church-state authority crisis of the sixteenth century. Its legitimacy, however, rested at that time on the notion of divine right, whereby authoritative uses of power were grounded in the moral claims of religious loyalty. With the rise of nationalism in the eighteenth century, the moral basis shifted from the church to the people in the form of the nation, so that divine right gave way to popular sovereignty. It soon became evident that nationalism was exclusionary, and as an ideology it could be used to justify heinous atrocities against "others" who did not belong to the national group controlling the state.

Sovereignty today is the subject of much debate, with some calling for the "deterioralization" of sovereignty and others heralding the erosion of the sovereign state in favor of a combination of simultaneously more local and more global societal relations.

Space exploration

The sociocultural status of space exploration has been contested for many years and remains uncertain. Although astronomy and related sciences have benefited greatly from the world’s space programs, space exploration was motivated not by scientific curiosity but by the romanticism of a social movement and by competition between prestige-conscious nations. By the end of the nineteenth century, astronomy possessed a rough picture of the solar system, including the knowledge that objects like the Moon and Mars were worlds somewhat comparable to the earth, but realistic means for space travel had not yet been imagined. Then, autonomous intellectuals independently developed the correct theories for multistage liquid-fuel rockets.

**SOCIAL ORIGINS**

Konstantin Tsiołkovsky (1857–1935) was an impoverished schoolteacher in Russia who devoted many years of socially isolated work to developing fruitful ideas about spaceflight. American Robert H. Goddard (1882–1945) independently developed many of the same ideas, and possessing greater resources was actually able to build a working liquid-fuel rocket in 1926. Romanian-German Hermann Oberth (1894–1989) learned of the work of his colleagues just as he was about to publish his treatise, The Rocket into Planetary Space, in 1923. On the basis of the work of these pioneers, spaceflight societies were founded in Germany (1927), the United States (1930), Russia (1931), and Great Britain (1933). The German, U.S., and Russian groups independently duplicated Goddard’s working liquid-fuel rocket, although Goddard refused to cooperate with the others in the vain hope that he could develop unaided the technology to send an unmanned rocket to the moon. United only by publications and occasional visits, these groups formed an international social movement dedicated to space travel for transcendent motives that were neither economic nor political.

As the financial troubles of the Great Depression deepened, the space-travel movement struggled to survive. Especially in Germany, and later in the United States and Russia, the movement entered into a marriage of convenience with the military. The Treaty of Versailles ending World War I (1914–1918) had limited German artillery and aircraft but did not mention rockets. Members of the movement, notably Oberth’s young protégé Wernher von Braun (1912–1977), presented liquid-fuel rockets to the German army as effective weapons, although development of conventional solid-fuel rockets would have been a better choice for military purposes. Near the end of World War II (1939–1945), von Braun’s team completed development of the 300-mile-range V-2 rocket, demonstrating the potential of liquid-fuel technology for spaceflight. Starting with the launch of Sputnik I in 1957, the Soviet Union and the United States competed for international prestige through aggressive space programs, until the landing of the Apollo 11 lunar module on the moon in 1969.

On the basis of a huge library of technical and scholarly publications, the facts of the history of space exploration to date are clear, but the social-scientific inter-
interpretation is hotly debated. The view around 1960 was that international propaganda competition was the main driver, as has been summarized by Vernon van Dyke (1964). Amitai Etzioni (1965) argued that the American space program was a useless extravagance through which the military-industrial complex looted the national treasury. Then, John Logsdon (1970) argued that President John F. Kennedy’s (1917–1963) decision to go to the moon was a means for reviving the political spirit of his New Frontier program after defeats in 1961 with the aborted Bay of Pigs invasion of Cuba and in a meeting with the Soviet leader Nikita Khrushchev (1894–1971). William Bainbridge (1976) took the argument one step further, suggesting that in Germany and the Soviet Union, as well as in the United States, leaders of the transcendental spaceflight movement had cleverly manipulated beleaguered political leaders to invest in space as a symbolic solution to their inferiority in competition with other leaders. Michael Neufeld (1996) has argued against this thesis in the case of Germany, asserting that technically competent military engineers possessed a correct estimation of the military potential of the technology. Walter McDougall (1985) argued against this view in the case of the Soviet Union, stating that Marxist ideology naturally supported visionary technological projects. Most recently, Logsdon (2006) has argued that the American space program has been trapped in a vicious circle, as members of the movement convince political leaders to undertake technically demanding projects, but the public is not willing to invest enough to make them successful.

SOCIETAL IMPLICATIONS

Public opinion has long been generally favorable toward the space program but has never been a driving force in motivating development of the technology. In October 1947, a Gallup poll asked 1,500 Americans, “How long do you think it will be before man will be able to fly to the moon?” Only 21 percent guessed a particular year, 38 percent said “never,” and the remainder had nothing to say on the topic. Throughout the Apollo program, a majority tended to feel the project was not worth the cost. Americans’ enthusiasm for the actual moon landing faded fast after 1969, possibly accelerated by a general loss of confidence in science and technology that prevailed until the mid-1970s. Since then, majorities have tended to feel that the National Aeronautics and Space Administration (NASA) was doing a good job, but they give space exploration a low priority for funding. The responses of 1,400 Americans to the General Social Survey in 2004 were typical. Only 14.3 percent wanted funding increased, 43.4 percent wanted it kept at current levels, 36.8 percent wanted funding reduced, and the remaining 5.5 percent had no opinion.

Around 1970 there was considerable discussion of the potential terrestrial benefits of space, especially the second-order consequences from technology transfer, often called spin-offs. These were popularly conceptualized as distinct inventions made in the space program that found valuable uses in society. Many people count Tang powdered fruit drink, Teflon coatings on frying pans, and Velcro fasteners among these, but all existed before the space program. Real spin-offs actually are rare, but their stories fit popular misconceptions about how technological progress occurs, so they are legends that gain strength in the retelling. Far more important are the intended applications of space technology, the most prominent of which are communications satellites, navigation satellites (Global Positioning System), meteorology satellites, and military reconnaissance satellites. Difficult to measure, but probably of equal value, is the general stimulus to scientific and technological development achieved by the space program through increasing the technical expertise in the population, widely disseminating abstract technical ideas that may contribute to innovations far from their original sources, and inspiring young people to study science.

When Bainbridge (1991) asked two thousand students at Harvard University in 1986 to identify the possible goals for the space program, they came up with a list of 125 goals that could be clustered into groups that served different values. Some goals were technical and economic, including the benefits of satellites listed above, spin-offs, possible manufacturing in the vacuum and weightlessness of space, new knowledge for sciences like physics and astronomy, and preservation of the earth’s environment. A different set of goals stressed emotional and idealistic values, such as spiritual fulfillment, personal inspiration, artistic and aesthetic transcendence, satisfaction of curiosity, and the building of world harmony. A small group of items concerned national pride, defense, and military capabilities in space. Finally, a number of far-out but reasonably popular goals envisioned colonization of the solar system and the discovery of extraterrestrial life.

The early decades of the twenty-first century appear to be a transition period, in which predictions would be especially hazardous. China has launched men into orbit, thereby demonstrating the quality of its technology, especially to the propaganda disadvantage of Japan, which has pursued a half-hearted and largely unsuccessful space program. Both Russia and the European Union have well-established space launch capabilities but lack ambitious goals. After failing twice to develop a successor to the space shuttle in the National Aerospace Plane and the X-33, and running more than fifteen years overdue in completing the space station, the U.S. space program clearly required fundamental redirection. The initial phase of reorganization, announced in 2004, severely cut back scientific research and technological development in favor of
very long-term plans for adventurous but poorly motivated human voyages to the Moon and Mars.

As any science fiction fan would be happy to explain to any social scientist willing to listen, the long-term social implications of space exploration could possibly be profound. Despite daunting technical and economic hurdles, the colonization of Mars and of several large satellites in the solar system could lead to a time when more humans lived off the Earth than on it. Some think we will transform ourselves radically to become better adapted to those alien environments and better prepared for interstellar travel. If so, space travel could bring about a new adaptive radiation event comparable to that which produced the human species five million years ago in East Africa, what the science fiction writer Alfred Bester (1913–1987) called “arrival of the fittest” in his novel, The Stars My Destination (1956). If the social scientist scoffed at such ideas, the science fiction fan might comment there must have been chimpanzees five million years ago who scoffed as well.

SPANISH CIVIL WAR
The Spanish Civil War broke out on July 17, 1936, as a result of the revolutionary process begun under the democratic Second Republic of Spain, which had been inaugurated in 1931. Democracy had brought large-scale political and social mobilization, while the left launched a series of four revolutionary insurrections between 1932 and 1934. In 1935 an alliance of the moderate and the revolutionary left formed a Popular Front that won the election of February 1936. This produced a weak minority government of the moderate left that could not restrain the revolutionaries, whose violence, disorder, seizure of property, and corruption of electoral processes provoked a military revolt.

Though Spanish political society was strongly polarized between right and left, each polarity was badly fragmented. The military revolt brought scarcely more than half the army out in revolt, though it was assisted by rightist militia. The leftist Republican government in power abandoned constitutional rule and engaged in what was called “arming the people,” which meant giving weapons and de facto power to the revolutionary organizations.

The result was the Spanish revolution of 1936–1937, the most intense and spontaneous outburst of worker revolution seen in modern Europe, not excepting the Russian Revolution of 1917. It collectivized much farmland and most of urban industry, and it was marked by an extensive Red Terror—the mass execution of political opponents, directed against all conservative organizations, and especially the Catholic Church—which destroyed countless churches. Nearly 7,000 clergy were killed, and at least 55,000 people perished in the Republican zone.
After two months, the military insurgents elected General Francisco Franco as their commander-in-chief. Franco also acted as dictator and permanent chief of state. By the second week of the Civil War, he had successfully sought military assistance from Nazi Germany and Fascist Italy, and he mounted a military drive on Madrid. The rebels quickly termed themselves Nationalists and mounted a savage repression of their own, which was more concerted and effective than that of the Republicans and eventually claimed even more victims.

General Franco organized a single-party state, partially modeled on that of Fascist Italy, in April 1937. He combined the Spanish fascist party with rightist groups to form the Falange Española Tradicionalista (Traditionalist Spanish Phalanx, or FET). Franco succeeded in establishing almost complete political unity among the rightist forces, enabling him to concentrate almost exclusively on the war effort, and in the process he developed a more effective and professionally led military force than did his opponents.

The revolutionary Republic proved ineffective militarily, relying on disorganized revolutionary militia. After the first two weeks it lost battle after battle, resulting in the organization of a new Republican government on September 4, 1936, led by the Socialist Francisco Largo Caballero. It eventually included all the leftist forces in a single government and began the creation of a new centralized Ejército Popular (People’s Army).

Though France was led by a Popular Front government at this time, it was becoming dependent on Great Britain, which counseled against involvement in Spain. The French government therefore took the lead in organizing the Non-Intervention Committee, which gained the collaboration of nearly all European governments and took up deliberations in London in September 1936, though it was unsuccessful in ending the involvement in the war of the three major European dictatorships.

Germany and Italy were already intervening on behalf of Franco, and the Republicans urgently requested military assistance from the Soviet Union, the only other revolutionary state in Europe. Stalin finally decided to send assistance in September 1936, and Soviet military assistance began to arrive soon afterward. This assistance was paid for by shipping most of the Spanish gold reserve (the fifth largest in the world) to Moscow. Late-model Soviet planes and tanks, which arrived in large quantities, outclassed the weaponry provided by Hitler and Mussolini. These weapons, together with hundreds of Soviet military specialists, were accompanied by the first units of the International Brigades, a volunteer force organized by the Communist International, which eventually numbered approximately 41,000. By the end of 1936 the war was turning into a stalemate, and it promised to become a long struggle of attrition.

In this situation, the Spanish Communist Party, which had been weak prior to the war, expanded rapidly. Soviet assistance helped it become a major force on the Republican side, emphasizing the importance of restraining the revolution of the extreme left and concentrating all resources on the military effort. This provoked great tension, leading to the “May Days” of May 1937 in Barcelona, the center of the revolution. This was a mini–civil war within the civil war, with the extreme revolutionary left fighting the more disciplined forces of the Communists and the reorganized Republican state. The latter dominated, leading to the formation that same month of a new Republican government led by the Socialist Juan Negrín, which deemphasized the socioeconomic revolution and sought to concentrate all its activity on the military effort.

The Soviet escalation of military intervention in October 1936 was quickly countered by a counter-escalation from Mussolini and Hitler, who sent an Italian army corps of nearly 50,000 men and a 90-plane German aerial unit, the Condor Legion, to Spain. This guaranteed that Franco would continue to receive the support necessary to maintain the military initiative. In 1937 he conquered the Republican northern zone, and in April 1938 his army sliced through Aragon to the Mediterranean, dividing the remaining Republican zone in two. During the conquest of the northern zone, the most famous (and infamous) incident of the war occurred. This was the bombing of the Basque town of Guernica by German and Italian planes in April 1937.

Though Mussolini desired a quick and complete Nationalist victory to strengthen Italy’s position in the Mediterranean, Hitler was in no hurry. He preferred that the Spanish war continue for some time. It had become the main focus of European diplomacy during 1936-1937, and it served to distract attention from the rearmament of Germany and the beginning of its expansion in central Europe. The French government covertly supported the Republican cause in a policy of “relaxed intervention,” which served as a conduit for military supplies from the Soviet Union and other countries. By 1937, Stalin was in turn increasingly distracted by the Japanese invasion of China. In 1938 he sought disengagement from Spain, but he could find no terms that would not involve a loss of face.

Franco’s forces slowly but steadily gained the upper hand. His government in the Nationalist zone maintained a productive economy and a relatively stable currency. The revolutionary Republican zone, by contrast, was wracked with inflation and suffered increasingly severe shortages, producing widespread hunger by 1938. The Communists,
in turn, developed a political and military hegemony under the Negrín government, though never complete domination. The policy of both Negrín and the Communists was to continue resistance to the bitter end, hoping that a general European war would soon break out, during which France would come to the relief of the Republicans. This was increasingly resented by the other leftist parties, however, who finally rebelled in Madrid in March 1945, overthrowing Negrín and the Communists, and then soon surrendering to Franco, who declared the end of the war on April 1, 1939.

The Spanish Civil War was a classic revolutionary-counterrevolutionary civil war, somewhat similar to those that occurred in eastern and southeastern Europe after each of the world wars. It became a highly mythified event, often presented as a struggle between “fascism and democracy,” “fascism and communism,” or “Christian civilization and Asian barbarism.” It has also been viewed as the “opening battle of World War II (1939–1945).” All such epithets are exaggerated, however. While there was fascism on the side of Franco’s Nationalists, there was no democracy on the Republican side. In Spain, Hitler and Stalin were on opposite sides, but they joined forces in August-September 1939 to begin World War II in Europe. Germany and Italy did gain their goals in Spain, however, while Soviet policy failed.

Militarily, the war was notable for the introduction of late-model weaponry, especially new warplanes and tanks. The Soviet military studied the war with great thoroughness, but they sometimes drew the wrong conclusions from it, as did some other countries. Germany learned important lessons on the use of combined arms and air-to-ground support, but it failed to improve its armored forces. The victorious Franco regime skirted with involvement in World War II, but it never entered that conflict and endured until Franco’s death in 1975.

SPATIAL MAPPING
SEE Geography.

SPATIAL THEORY
Spatial theory is built on the concept of distance; this distance may be of an economic or ideological form. The foundations of spatial analysis span many disciplines, such as economics, urban studies, and political science. The seminal paper by Hotelling (1929) studied the equilibrium location of two sellers of a homogenous product in a linear town where all consumers are located on a single road. Hotelling’s model is based on physical distance and demonstrates that if the sellers compete only in terms of location (spatial competition) and they are identical in all other dimensions such as quality, costs, and prices, then their optimum location will be the median of the town. Consumers try to minimize travel time when they choose between similar stores. The result is that the stores locate next to each other at the center of the town to capture the most customers. The implicit assumption of spatial models is that people are motivated mainly by self-interest—firms maximize profit and consumers maximize utility.

The notion of space can be extended beyond physical space to include “position” in product characteristics, as described by Lancaster (1979), and “position” in political platforms, as elaborated by Downs (1957). Similarly, in Chamberlain’s (1933) model of monopolistic competition, space is seen as a tool to derive the demand curve faced by the monopolistic firm. Although Hotelling and Smithies (1941) are credited with originating the idea, Downs established spatial theory as a conceptual tool. The modern applications of spatial theory in economics, urban studies, and political science are based on the trade-offs...
between gains and losses as a result of changes in spatial position. Smithies modified Hotelling’s model by introducing elastic demand so that people at the edges of town might stop shopping at the store if it moved too far to the center. Under perfect inelastic demand conditions, as suggested by Hotelling, consumers are assumed to travel to the center of the town regardless of the opportunity cost of transportation. To introduce a trade-off between the access and transportation cost, Smithies suggested that transportation costs lead to elastic demand at each point on the linear road. Thus, when consumers face an inverse demand function with respect to the distance from the center, they will stop traveling to the center if the cost of travel outweighs the benefit of access. Mills (1972) suggested that allocation of land to differing uses is determined primarily by transportation costs. He argued that variability in transportation costs is a key determinant in the distribution of people across a metropolitan area. The lower transportation costs are, the more decentralized the area is.

Political applications of the spatial model closely followed the spatial theories of economic competition. The electoral models developed by Downs essentially adopt the same principles that economists and social choice theorists use to analyze people’s actions in the marketplace and collective decision making. The economic concept of locational equilibrium has been applied to the political world. Downs assumed that voters were distributed over policy dimensions and that political parties played the role of stores. The tendency of competing businesses toward imitation is applied to political parties during elections. When voters vote for the party closest to them on a single policy dimension, the parties converge to the median voter’s preferences. Since the goal of a political party is to maximize votes, parties and candidates purposefully take positions in the center of the distribution of voter preferences. Restricting issues to a single policy dimension and assuming single-peaked preferences, the expected result is a spatial equilibrium at the position of the median voter (Downs 1957; Black 1958). Since the voters choose to support the candidate nearest to them on the ideological scale, the parties and candidates should adopt platforms that appeal to the median voter to win a majority of the votes. The Downs/Hotelling spatial theory of competition assumes that each voter votes for the candidate from whom he or she derives the highest utility. Down’s model is an example of the social choice theory; it introduces the electoral trade-off between the number of extremists each party loses by moving toward the center, as compared with the number of moderates it gains. As parties move toward the center of the political spectrum, the voters at the extremes are less likely to identify with mainstream parties and thus choose extremist alternatives or abstention.

Modern monocentric models were developed in the 1960s, largely by Alonso (1964), Muth (1969), and Mills (1972). These models assume the existence of a center in a geographic space to which access is scarce, and therefore valuable. To be close to the center for better access, businesses and consumers bid for land. Land prices are inversely related to distance to the center. Businesses and consumers face a trade-off between land prices and transportation costs. Those who value access to the center more will outbid the others and face higher land prices and lower transportation costs. In Beckmann’s (1973) family choice model, distance to the center is inversely related to the number of dependents in a family unit. Similarly, the smaller size of the ratio of wage earners to family size determines an equilibrium location further from the center. Monocentric models are not concerned with why access is desirable but rather with its consequences, especially the manner in which the market allocates access. However, the need to interact turns out to be sufficient to generate a dense center that exhibits a single peaked-distribution of (homogenous) people across locations. There are many theories of why people want to develop and maintain lasting and positive relations. Beckmann (1976) was the first to focus on the trade-off between the average distance to those with whom one interacts and the amount of the land one consumes. In this model, the city or downtown emerges as a magnet for social relations.

Note that the spatial electoral model (Downs 1957) and the monocentric model (Alonso 1964; Muth 1969; Mills 1972) are also single-peaked as long as the voters are voting on one issue, the city has one center, and the spatial competition has only one dimension. In the real world, however, political discourse and campaign issues seldom fall into a single dimension and goods are different in other dimensions than distance. In this case single-peaked distributions are not possible and multiple equilibria result instead.

The Spearman rank correlation coefficient is a nonparametric (distribution-free) rank statistic proposed by Charles Spearman in 1904. It is a measure of correlation that captures the strength of association between two variables without making any assumptions about the frequency distributions of the underlying variables.

The computation of the Spearman rank correlation coefficient requires first that the values of the two variables be assigned ranks. When the data are not initially ranked, the first step is to separately rank the two variables $X$ and $Y$ under examination. Then the Spearman coefficient is calculated as the ordinary Pearson correlation coefficient $r$ between the ranked values of $X$ and $Y$. After ranking the two variables, for each case $i$ we take the difference $d_i = X_i - Y_i$ for each pair, and then we calculate the Spearman coefficient. This coefficient of rank correlation measures the degree of association between the two sets of ranks. The formula of this statistic is

$$r_s = 1 - \frac{6 \sum d_i^2}{n(n^2-1)}$$

where $r_s$ = the Spearman rank correlation coefficient, $d_i$ = the difference between each pair of ranks of corresponding values of the variables $X$ and $Y$, and $n$ = the number of pairs of values in the sample.

There are two properties of this coefficient. First, the values of the Spearman correlation coefficient will always vary between $-1$ and $1$. When the value of the coefficient is $1$, there is a perfect positive correlation or direct correlation. That is, large values of the one variable, for example, $X$, are associated with large values of the other, for example, $Y$, and small values of the $X$ variable are associated with small values of the $Y$ variable. When the coefficient is $-1$, there is a perfect negative correlation or indirect correlation. In this case, large values of the $X$ variable are associated with small values of the $Y$ variable and vice versa. When the value is equal to zero, it means that there is no relationship or correlation. This statistic shows only that two variables $X$ and $Y$ correlate positively or negatively; it does not offer any indication that one variable affects the other.

The second property of the Spearman rank correlation, and of its parametric counterpart, is that it is a pure number without units or dimensions. In using this coefficient we deal with two sets of ranks assigned to the variables $X$ and $Y$. The original observations on the variables may be ranks, or they may be numerical values ranked by magnitude.

In addition to interpreting the magnitude and the direction of a correlation coefficient, the significance of a given value of correlation should also be tested. The null hypothesis states that no correlation exists and that whatever value of correlation is found between the two examined variables is due to sampling error.

A modern approach to testing the hypothesis that the value of the Spearman coefficient is significantly different from zero is to calculate the probability that it would be greater than or equal to the observed $r$ by using a permutation test. This method is superior to the traditional ones in most cases, even when the dataset is large, because modern computing has the power to generate permutation.

The traditional approach for determining significance is still widely used. It involves the comparison of the calculated $r$ with published tables for various levels of significance. It only requires that the tables have the pertinent values for the desired ranges.

An alternative approach for samples of large sizes is the approximation to the Student’s $t$-distribution that is given by the following formula:

$$t = r_s / [(1 - r_s^2) / (n - 2)]^{1/2}$$

When the sample size ($n$) is less than 10, the above is not appropriate. For values of ($n$) less than 10, table 1 shows the critical values of $r_s$ required for the significance
at the 0.05 level for both a nondirectional and a directional test.

APPLICATIONS AND SHORTCOMINGS

The Spearman rank correlation coefficient can be used when the normality assumption of the two examined variables’ distribution is violated. It also can be used when the data are nominal or ordinal. It may be a better indicator that a relationship exists between two variables when the relationship is nonlinear, even for variables with numerical values, when the Pearson correlation coefficient indicates a low or zero linear relationship. When there are three or more conditions, a number of subjects are all observed in each of them, and we predict that the observations will have a particular order. In this case, a generalization of the Spearman coefficient is useful.

As with all other nonparametric or distribution-free procedures or tests, the Spearman rank correlation coefficient is less powerful than its parametric counterpart, the Pearson product-moment correlation coefficient. In addition, there is no evidence of causality between the two variables that have been found to be related by this coefficient.

ALTERNATIVE CORRELATION COEFFICIENTS

There are other examples of correlation coefficients, including the Pearson product-moment correlation coefficient, which is used for making inferences about the population correlation coefficient, assuming that the two variables are jointly normally distributed. When this assumption cannot be justified, then a nonparametric measure such as the Spearman correlation coefficient is more appropriate. The Pearson correlation coefficient measures the linear association between two variables that have been measured on interval or ratio scales. The formula that determines the Pearson product-moment correlation coefficient \( r_{xy} \) is

\[
r_{xy} = \frac{\sum_{i=1}^{n} (X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^{n} (X_i - \bar{X})^2} \sqrt{\sum_{i=1}^{n} (Y_i - \bar{Y})^2}}
\]

The significance of \( r \), where the null hypothesis states that no correlation exists between the two variables \( X \) and \( Y \) \((r_{xy} = 0)\), is found by the following \( t \)-statistic, with \((n - 2)\) degrees of freedom:

\[
t = \frac{r(n - 2)^{1/2}}{(1 - r^2)^{1/2}}
\]

Another measure of degree of concordance that is closely related to the Spearman correlation coefficient is the Kendall tau rank correlation coefficient, given by the formula

\[
\tau = \frac{1}{n(n-1)} \sum_{i<j} c_{ij}
\]

Similar to the Spearman coefficient, Kendall’s tau lies between –1 and 1. When it is equal to +1, we assume that there exists complete concordance, whereas when it is equal to –1, there exists complete disagreement. This Kendall tau \( (\tau) \) coefficient uses the same data as the Spearman correlation coefficient \( (r) \) but differs arithmetically, so they are not exactly similar.

In order to calculate the tau \( (\tau) \) coefficient we go through the following steps.

1. We rank the values of variable \( X \) from 1 to \( n \); similarly, we rank the values of variable \( Y \), both in an ascending order.
2. We make pairs for every ranked value of \( X_j \) the equivalent \( Y_j \).
3. We compute the variable \( S \), which is equal to \( S = \sum c_{ij} \), where \( c_{ij} = 1 \) if \( X_i \) and \( X_j \) have the same rank with the \( Y_i \) and \( Y_j \) and \( c_{ij} = -1 \) in the opposite case.
4. If there are no same-value cases among the \( X_i \) and \( Y_i \) (or there are few compared to the sample size \((n)\)), then Kendall’s tau coefficient is equal to \( \tau = 2S / [n(n-1)] \).

An advantage of the Kendall tau coefficient compared to the Spearman correlation coefficient is that the former can be generalized in order to determine the Kendall partial correlation coefficient, which is equivalent to the Pearson partial correlation coefficient in cases where nonparametric statistics are appropriate.
Another correlation coefficient, the correlation coefficient $C$ of rank matrices (or “double-entrance matrix”), examines the degree of dependence between two variables $X$ and $Y$, despite the facts that these variables could be ranked or not, that they could be continuous or discontinuous, and that they could have normal distributions or not. It can be calculated by the formula:

$$C = \left[ \frac{X^2}{(n + X^2)} \right]^{\frac{1}{2}}$$

and it follows the chi-squared ($\chi^2$) distribution with $v = (r - 1)(q - 1)$ degrees of freedom, where $r$ and $q$ are the numbers of rows and columns, respectively, of the rank matrix under examination. In order to test the null hypothesis that $C = 0$, or that the two variables $X$ and $Y$ do not have a significant relationship, we calculate the $\chi^2$ and the $X^2$, which is the critical value. The latter can be found in the tables of the $\chi^2$ distribution for $v = (r - 1)(q - 1)$ degrees of freedom. If $\chi^2 < X^2$, then the null hypothesis is rejected.

SPECIFICATION

The term specification is used in economics to denote the choice of a model in the context of empirical modeling. Unfortunately, the use of the term since the late 1950s (Theil 1957, Leamer 1990) is confusing because different types of models are conflated; the crucial confusion being between a statistical (a set of probabilistic assumptions) and a structural (substantive) model. The distinction between these two types of models is important because they raise very different issues with respect to the premises of inference in empirical modeling (see Spanos 2006a).

THEORY AND STRUCTURAL MODELS

It is widely recognized that most stochastic phenomena (the ones exhibiting chance regularity patterns—see Spanos 1999) are commonly influenced by a very large number of contributing factors, and that explains why theories are often dominated by *ceteris paribus* clauses. The idea behind a theory is that in explaining the behavior of a variable, say $y_k$, one demarcates the segment of reality to be modeled by selecting the primary influencing factors $x_k$, cognizant of the fact that there might be numerous other potentially relevant factors $\xi_k$ (observable and unobservable) that jointly determine the behavior of $y_k$ via a theory model:

$$y_k = h^*(x_k; \xi_k), k \in \mathbb{N} = \{1, 2; \ldots, n; \ldots\}$$

where $h^*(\cdot)$ represents the true behavioral relationship for $y_k$. The guiding principle in selecting the variables in $x_k$ is to ensure that they collectively account for the systematic behavior of $y_k$ and the unaccounted factors $\xi_k$ represent nonessential disturbing influences which could only have a nonsystematic effect on $y_k$. This reasoning transforms (1) into a structural model of the form:

$$y_k = h(x_k; \varphi) + c(x_k; \delta_k), k \in \mathbb{N}.$$  

By definition the error term process is:

$$e(x_k; \xi_k) \overset{\text{control}}{=} e_k \overset{\text{design}}{=} \text{IID}(0, \sigma^2), k = 1, 2, \ldots, n.$$  

and represents all unmodeled influences, intended to be a nongeneric white-noise (nonsystematic) stochastic process; that is, $\{e(x_k; \xi_k), k \in \mathbb{N}\}$ has (i) mean zero, (ii) variance $\sigma^2 < \infty$; (iii) uncorrelated over $k$; and (iv) orthogonal to $h(x_k; \varphi)$ for all possible values $(x_k, \xi_k) \in \mathbb{R}_k \times \mathbb{R}_\xi$. Note that (iv) aims to demarcate a “near isolation” condition for the phenomenon of interest.

In summary, a structural model provides an “idealized” substantive description of the phenomenon of interest, in the form of a “nearly isolated” mathematical system (Spanos 1995). The specification of a structural model comprises several choices: (a) the demarcation of the segment of the phenomenon of interest to be captured; (b) the important aspects of the phenomenon to be measured, and (c) the extent to which the inferences based on the structural model are germane to the phenomenon of interest.
The kind of errors one can probe for in the context of a structural model concern the choices (a)–(c), which include the form of \( h(x_t; \varphi) \) and the circumstances that render the error term \( \varepsilon(x_t, \xi_k) \) potentially systematic, such as the omission of relevant factors, say \( \psi_k \), in \( \xi_k \) that might have a systematic effect on the behavior of \( y_t \) (see Spanos 2006b for further discussion).

The problem with (3) is that assumptions (i)–(iv) of the structural error are nontestable because their assessment would involve verifying these assumptions for all possible values \( (x_k, \xi_k) \in \mathbb{R}_k \times \mathbb{R}_k \). To render them testable one needs to embed this structural into a statistical model with a generic error term; a crucial move that often passes unnoticed. Not surprisingly, the nature of the embedding itself depends crucially on whether the data \( Z = (z_1, z_2, \ldots, z_n) \) are the result of an experiment or they are nonexperimental (observational) in nature.

### STATISTICAL MODELS WITH EXPERIMENTAL DATA

In the case where one can perform experiments, “experimental design” techniques might allow one to operationalize the “near isolation” condition, including the ceteris paribus clauses, and ensure that the error term is no longer a function of \( z_t \) for \( t \in T \), but takes the generic form

\[ c(x_k, \xi_k) = \alpha_k - \text{IID}(0, \sigma^2), \quad k = 1, 2, \ldots, n, \tag{4} \]

where “IID” stands for Independent and Identically Distributed. For instance, randomization and blocking are often used to “neutralize” the phenomenon from the potential effects of \( \xi_k \) by ensuring that these uncontrolled factors cancel each other out (Fisher 1935). As a direct result of the experimental “control,” via (4) the structural model (2) is essentially transformed into a statistical model

\[ y_t = \beta_0 + \beta|x_t| + \varepsilon_t, \quad \varepsilon_t \sim \text{IID}(0, \sigma^2), \quad k = 1, 2, \ldots, n. \tag{5} \]

The statistical error terms in (5) are qualitatively very different from the structural errors in (2) because they no longer depend on \( (x_k, \xi_k) \in \mathbb{R}_k \times \mathbb{R}_k \). The most important aspect of embedding the structural (2) into the statistical model (5) is that, in contrast to (i)–(iv) for \( \{c(x_k, \xi_k), k \in \mathbb{N}\} \), the probabilistic assumptions \( \varepsilon_t \sim \text{IID}(0, \sigma^2) \) concerning the generic statistical error term are rendered testable. That is, (4) has operationalized the “near isolation” condition and the statistical model has been created as a result of the experimental design and control.

A crucial consequence of (4) is that the informational universe of discourse for the statistical model (5) has been demarcated to the probabilistic information relating to the observables \( Z_k = (y_t, X_k) \) as described by the joint distribution \( D \{Z_1, Z_2, \ldots, Z_T; \varphi\} \). A statistical model can be viewed as a parameterization of the presumed probabilistic structure of the process \( \{Z_t, t \in T\} \) (Spanos 1986, 1999). This probabilistic structure is chosen so as to render the observed data \( Z = (z_1, z_2, \ldots, z_n) \) a truly typical realization thereof. This introduces into the empirical modeling a probabilistic perspective which treats the data as realizations of generic stochastic processes devoid of any substantive information.

In contrast to a structural model, once \( Z_t \) is chosen by some theory or theories, a statistical model relies exclusively on the statistical information in \( D \{Z_1, Z_2, \ldots, Z_T; \varphi\} \) that “reflects” the chance regularity patterns exhibited by the data. Hence, a statistical model acquires a life of its own in the sense that it constitutes a self-contained generic generating mechanism defined exclusively in terms of the observables \( Z_k = (y_t, X_k) \). For example, in the case where \( h(x_t; \varphi) = \beta_0 + \beta_1 x_t \), the error assumptions \( \varepsilon_t \sim \text{NIID}(0, \sigma^2) \) give rise to the Gauss Linear model which is given in table 1 (Spanos 1986).

In summary, a statistical model constitutes an “idealized” probabilistic description of a stochastic process \( \{Z_t, t \in T\} \) giving rise to data \( Z \) in the form of an internally consistent set of probabilistic assumptions chosen to ensure that this data constitute a “truly typical realization” of \( \{Z_t, t \in T\} \). Specification for the statistical model refers to choosing a parameterization and an associated complete set of testable probabilistic assumptions constituting the premises of inference. Specification error denotes departures from assumptions [1]–[5].

### STATISTICAL MODELS WITH OBSERVATIONAL DATA

This is the case where the observed data on \( (y_t, x_t) \) are the result of an ongoing data generating process, undisturbed by any experimental control or intervention. In this case the route followed in (4), in order to render the statistical error term \( (a) \) free of \( (x_k, \xi_k) \), and \( (b) \) nonsystematic in a statistical sense, is no longer feasible. However, as shown in Spanos (1986), sequential conditioning provides a general way to transform an arbitrary stochastic process \( \{Z_t, t \in T\} \) into a martingale difference process, a modern form of a white-noise process. This provides the key to an alter-

---

**Table 1 – The Gauss Linear (GL) Model**

\[ y_t = \beta_0 + \beta|x_t| + \varepsilon_t, t \in \mathbb{N}. \]

1. Normality: \( y_t \sim \text{N}(0, \sigma^2) \).
2. Linearity: \( c(x_t) = \beta|x_t| + \varepsilon_t \) is linear in \( (\beta_0, \beta_1) \).
3. Homoskedasticity: \( \text{Var}(y_t) = \sigma^2 \), free of \( x_t \).
4. Independence: \( (y_t, t \in \mathbb{N}) \) is an independent process.
5. \( t \)-invariance: \( \theta = (\beta, \varphi, \sigma^2) \) do not vary with \( t \).
native approach to specifying statistical models in the case of nonexperimental data by replacing the controls and interventions with the choice of the relevant conditioning information set \( D \), that would render the error term non-systematic—a martingale difference. The technical aspects of specifying statistical models using sequential conditioning are beyond the scope of the present discussion (Spanos 2006b), but an example of how one can specify a statistical model as a reduction from \( D (Z_i, \ldots, Z_T, \varphi) \) can shed some light on its practical aspects.

The Normal/Linear Regression (LR) model results from a reduction of \( D (Z_i, \ldots, Z_T, \varphi) \) by assuming that \( \{Z_t, t \in T\} \) is a NIID process. These reduction assumptions ensure that the appropriate conditioning information set is \( D_i = \{X_t = x_t\} \), giving rise to a statistical error term:

\[
(a_i | X_t = x_t) - \text{NIID}(0; \sigma^2); k = 1, 2, \ldots, n.
\]

This is analogous to (4) in the case of experimental data, but now the error term has been operationalized by a judicious choice of the conditioning information set \( D_i = \{X_t = x_t\} \). The complete specification of the Linear Regression model is similar to the Gauss Linear model (table 1), but instead of \( D (y; \theta) \), the underlying distribution is \( D (y | X_t; \theta) \)—assumptions [1]–[5] pertain to the probabilistic structure of \( \{y_t | x_t = x_t\}, t \in T \} \) (Spanos 1986). In this sense, \( D (y | X_t; \theta) \) brings to the table the statistical information which supplements, and can be used to assess the appropriateness of, the substantive subject matter information carried by the structural model.

CONFRONTING SUBSTANTIVE WITH STATISTICAL INFORMATION
An important aspect of embedding a structural into a statistical model is to ensure (whenever possible) that the former can be viewed as a reparameterization/restriction of the latter. The structural model is then tested against the benchmark provided by a statistically adequate model. Identification refers to being able to define \( \varphi \) uniquely in terms of \( \theta \). Often \( \theta \) has more parameters than \( \varphi \) and the embedding enables one to test the validity of the additional restrictions, known as overidentifying restrictions (Spanos 1990).

SPECIFICATION ERROR
In the context of a statistical model, specification error means that at least one of the key features or assumptions of the model is incorrect. In consequence, estimation of the model may yield results that are incorrect or misleading. Specification error can occur with any sort of statistical model, although some models and estimation methods are much less affected by it than others. Estimation methods that are unaffected by certain types of specification error are often said to be robust. For example, the sample median is a much more robust measure of central tendency than the sample mean because it is unaffected by the presence of extreme observations in the sample.

For concreteness, consider the case of the linear regression model. The simplest such model is

\[
y = \beta_0 + \beta_1 X + U,
\]

where \( Y \) is the regressand, \( X \) is a single regressor, \( U \) is an error term, and \( \beta_0 \) and \( \beta_1 \) are parameters to be estimated. This model, which is usually estimated by ordinary least squares, could be misspecified in a great many ways. Some forms of misspecification will result in misleading estimates of the parameters, and other forms will result in misleading confidence intervals and test statistics.

One common form of misspecification is caused by nonlinearity. According to the linear regression model (1), increasing the value of the regressor \( X \) by one unit always
increases the expected value of the regressand $Y$ by $\beta_1$ units. But perhaps the effect of $X$ on $Y$ depends on the level of $X$. If so, the model (1) is misspecified. A more general model is

$$Y = \beta_0 + \beta_1X + \beta_2X^2 + U,$$

(2)

which includes the square of $X$ as an additional regressor. In many cases, a model like (2) is much less likely to be misspecified than a model like (1). A classic example in economics is the relationship between years of experience in the labor market $(X)$ and wages $(Y)$. Whenever economists estimate such a relationship, they find that $\beta_2$ is positive and $\beta_1$ is negative.

If the relationship between $X$ and $Y$ really is nonlinear, and the sample contains a reasonable amount of information, then it is likely that the estimate of $\beta_1$ in (2) will be significantly different from zero. Thus we can test for specification error in the linear model (1) by estimating the more general model (2) and testing the hypothesis that $\beta_2 = 0$.

Another type of specification error occurs when we mistakenly use the wrong regressor(s). For example, suppose that $Y$ really depends on $Z$, not on $X$. If $X$ and $Z$ are positively correlated, we may well get what appear to be reasonable results when we estimate regression (1). But the correct regression

$$Y = \gamma_0 + \gamma_1Z + U,$$

(3)

should fit better than regression (1). A number of procedures exist for deciding whether equation (1), equation (3), or neither of them is correctly specified. These are often called nonnested hypothesis tests, and they are really a way of testing for specification error. In the case of (1) and (3), we simply need to estimate the model

$$Y = \beta_0 + \beta_1X + \beta_2Z + U,$$

(4)

which includes both (1) and (3) as special cases. We can test whether (1) is correctly specified by using the $t$-statistic for $\beta_2 = 0$, and we can test whether (3) is correctly specified by using the $t$-statistic for $\beta_1 = 0$.

Of course, it is possible that $Y$ actually depends on both $X$ and $Z$, so that the true model is (4). In that case, if we mistakenly estimated equation (1), we would be guilty of omitting the explanatory variable $Z$. Unless $X$ and $Z$ happened to be uncorrelated, this would cause the estimate of $\beta_1$ to be biased. This type of bias is often called omitted variable bias, and it can be severe when the correlation between $X$ and $Z$ is high.

Another very damaging type of specification error occurs when the error term $U$ is correlated with $X$. This can occur in a variety of circumstances, notably when $X$ is measured with error or when equation (1) is just one equation from a system of simultaneous equations that determine $X$ and $Y$ jointly. Using ordinary least squares in this situation results in estimates of $\beta_0$ and $\beta_1$ that are biased and inconsistent. Because they are biased, the estimates are not centered around the true values. Moreover, because they are inconsistent, they actually converge to incorrect values of the parameters as the sample size gets larger.

The classic way of dealing with this type of specification error is to use instrumental variables (IV). This requires the investigator to find one or more variables that are correlated with $X$ but not correlated with $U$, something that may or may not be easy to do. The IV estimator that results, which is also called two-stage least squares, is still biased, although generally much less so than ordinary least squares, but at least it is consistent. Thus, if the sample size is reasonably large and various other conditions are satisfied, IV estimates can be quite reliable.

Even if a regression model is correctly specified in the sense that the relationship between the regressand and the regressors is correct and the regressors are uncorrelated with the error terms, it may still suffer from specification error. For ordinary least squares estimates with the usual standard errors to yield valid inferences, it is essential that the error terms be uncorrelated and have constant variance. If these assumptions are violated, the parameter estimates may still be unbiased, but confidence intervals and test statistics will generally be incorrect.

When the error terms do not have constant variance, the model is said to suffer from heteroskedasticity. There are various ways to deal with this problem. One of the simplest is just to use heteroskedasticity-robust standard errors instead of conventional standard errors. When the sample size is reasonably large, this generally allows us to obtain valid confidence intervals and test statistics.

If the error terms are correlated, confidence intervals and test statistics will generally be incorrect. This is most likely to occur with time-series data and with data where the observations fall naturally into groups, or clusters. In the latter case, it is often a good idea to use cluster-robust standard errors instead of conventional ones.

When using time-series data, one should always test for serial correlation, that is, correlation between error terms that are close together in time. If evidence of serial correlation is found, it is common, but not always wise, to employ an estimation method that “corrects” for it, and there are many such methods. The problem is that many types of specification error can produce the appearance of serial correlation. For example, if the true model were (4) but we mistakenly estimated (1), and the variable $Z$ were serially correlated, it is likely that we would find evidence of serial correlation. The right thing to do in this case...
would be to estimate (4), not to estimate (1) using a method that corrects for serial correlation.

The subject of specification error in regression models and other statistical models has produced a vast body of research in statistics, econometrics, and other fields. A graduate-level textbook that covers this topic extensively is *Econometric Theory and Methods* (2004) by Russell Davidson and James MacKinnon. A less-advanced book that treats many of the same topics at a lower level is Jeffrey Wooldridge’s *Introductory Econometrics* (2006).

**SPECIFICATION TESTS**

The term specification tests is used in economics to denote tests for departures from the premises of inference in empirical modeling. This use of the term, however, is confusing because it conflates statistical with substantive specification errors (misspecifications), rendering the discussions of specification tests problematic (see Theil 1957).

In the context of a statistical model, the relevant misspecifications concern departures from the probabilistic assumptions constituting the statistical premises, such as [1]–[5] in Table 1.

In contrast, specification errors in relation to a structural model concern the model’s inadequacies in relation to: (a) the demarcation of the segment of reality to be modeled; (b) the crucial aspects of the phenomenon to be quantified; and (c) the extent to which the inferences based on the structural model are germane to the phenomenon of interest. In addition, reliable probing for such specification errors can only take place in the context of a statistically adequate model, that is, an estimated statistical model whose assumptions are (approximately) true for the data in question. Statistical inadequacy renders inference procedures (estimation, testing, prediction) unreliable because the procedures nominally differ from the actual error probabilities. A statistically adequate model provides reliable inference procedures to probe for substantive inadequacies.

Specification tests in the context of a structural model refer to assessing the adequacy of the three choices described above, including incongruous measurement and external invalidity (see Spanos 2006a). The quintessential form of a substantive specification error, however, is the omitted-variables problem. The issue is one of substantive inadequacy insofar as subject-matter information raises the possibility that certain influential factors \( W \) might have been omitted from the relevant factors \( X \), explaining the behavior of \( y \) (Leamer 1990). That is, omitting certain potentially important factors \( W \) may confound the influence of \( X \) on \( y \), leading to misleading inferences. Stating the problem in a statistically coherent fashion, one is comparing the following two models:

\[
[M_0]: y_t = x_t' \beta + u_t, \quad t \in \mathbb{N},
\]

\[
[M_1]: y_t = x_t' \gamma + \epsilon_t, \quad t \in \mathbb{N},
\]

using the hypotheses:

\[
H_0: \gamma = 0 \quad \text{vs.} \quad H_1: \gamma \neq 0.
\]

Models \( M_0, M_1 \) are based on the same statistical information \( \mathcal{Z} = (y, X, W) \), but \( M_0 \) is a special case of \( M_1 \) subject to the substantive restrictions \( \gamma = 0 \); \( M_0 \) can be viewed as a structural model embedded into the statistical model \( M_1 \). Assuming that the statistical model \( M_1 \) is statistically adequate, these statistical parameterizations can be used to assess the relationship between \( W, X \), and \( y \) by evaluating the broader issues of confounding and spuriousness using hypothesis testing (see Spanos 2006b).

</tbody>
</table>

*Table 1*
The statistical parameterizations associated with the two models, \( \varphi = (\beta, \sigma_u^2) \) and \( \theta = (\alpha, \gamma, \sigma_\varepsilon^2) \), take the form:
\[
\alpha = \beta - \Delta y, \quad \gamma = \delta - D \alpha,
\]
(4)
\[
\sigma_u^2 = \sigma_{11} - \sigma_{12} \sum_{12}^{-1} \sigma_{11} - \sigma_{12} \Delta y',\]
(5)
\[
\sigma_\varepsilon^2 = \sigma_{31} - \sigma_{12} \sum_{22}^{-1} \sigma_{21},
\]
where \( \sigma_{11} = \text{Var}(y), \sigma_{21} = \text{Cov}(X, y), \sigma_{31} = \text{Cov}(W, y), \sigma_{22} = \text{Cov}(X, W), \sigma_{32} = \text{Cov}(W). \) The textbook omitted-variables argument attempts to assess the seriousness of this unreliability using the sensitivity of the estimator \( \hat{\beta} = (XY)^{-1}XY \) to the inclusion/exclusion of \( W \), by tracing that effect to the potential bias/inconsistency of \( \beta \). Spanos (2006b) argues that the sensitivity of point estimates provides a poor basis for addressing the confounding problem. Although the confounding and spuriousness issues are directly or indirectly related to the parameters \( \alpha \) and \( \beta \), their appraisal depends crucially on the values of all three covariances \( (\sigma_{21}, \sigma_{31}, \sigma_{32}) \), and it can only be addressed adequately in a hypothesis-testing setup supplemented with a post-data evaluation of inference based on severe testing (see Spanos 2006b for details).

**Specification (mis specification) tests** in the context of a statistical model refer to assessing the validity of the probabilistic assumptions constituting the statistical model in question. Taking the normal/linear regression as an example (Table 1), specification error denotes any form of departures from assumptions [1]–[5] arising from viewing the observed data \( \{y, X\} \) as a truly typical realization of the stochastic process \( \{y_t \mid X_t = x\}, t \in \mathcal{M} \). This takes the form of Mis-Specification (M-S) tests, probing for departures from assumptions [1]–[5] (Spanos 1986, 1999).

To get some idea as to how these M-S tests can be viewed as probing for departures from the model assumptions, consider the linearity assumption [2]

**Linearity:** \( E(y_t \mid X_t = x) = \beta_0 + \beta_1 x \)

When this assumption is invalid, \( E(y_t \mid X_t = x) = \beta(x) \neq \beta_0 + \beta_1 x \), for some non-linear function \( \beta(\cdot) \). For the comparison to be operational, we need to specify a particular form for \( \beta(\cdot) \), say:

Nonlinearity \( \Rightarrow \) \( E(y_t \mid X_t = x) = \alpha_0 + \alpha_1 x + \alpha_2 \psi_i(x) \)

where \( \psi_i(x) \) includes, say, the second order terms \( (x^2 x^j), i, j = 2, \ldots, k \); note that \( x_{it} = 1 \). This comparison creates a situation of two competing models:

Model 1: \( E(y_t \mid X_t = x) = \beta_0 + \beta_1 x \)

Model 2: \( E(y_t \mid X_t = x) = \alpha_0 + \alpha_1 x + \alpha_2 \psi_i(x) \)

which, superficially, resembles the initial setup of models (1) and (2) but is fundamentally different in the sense that \( \psi_i(x) \) does not comprise different variables but functions of \( x \). Subtracting Model 1 from Model 2 gives rise to the following auxiliary regression:

\[
\hat{u}_t = (\alpha_0 - \hat{\beta}_0) + (\alpha_1 - \hat{\beta}_1) x_t + \alpha_2 \psi_i(x_t) + \epsilon_t
\]
(7)

where \( \hat{u}_t \) denotes the residuals from Model 1, which can provide a basis for testing the linearity assumption using the hypotheses:

\[
H_0 : \alpha_2 = 0 \quad \text{vs.} \quad H_1 : \alpha_2 \neq 0.
\]
(8)

The test of choice is the F-test (see Spanos 1986). Using the same type of reasoning, one can argue that the regression function will be affected by departures from other assumptions, such as [4] independence, leading to the auxiliary regression:

\[
\hat{u}_t = (\gamma_0 - \hat{\beta}_0) + (\gamma_1 - \hat{\beta}_1) x_t + \gamma_2 \epsilon_{t-1} + \epsilon_t
\]
(9)

where \( \epsilon_{t-1} := (y_{t-1}, x_{t-1}) \) (see Spanos 1986).

Pursuing the same reasoning further, one can derive an auxiliary regression to provide the basis for a joint test of how certain departures from assumptions [2] and [4] might affect the assumed regression function. This constitutes a combination of the previous two auxiliary regressions, leading to:

\[
\hat{u}_t = (\delta_0 - \hat{\beta}_0) + (\delta_1 - \hat{\beta}_1) x_t + \delta_2 \psi_i(x_t) + \delta_3 \psi_j(x_t) + \epsilon_t
\]
(10)

expressed in terms of the hypotheses:

\[
H_0 : \delta_2 = 0 \quad \text{vs.} \quad H_1 : \delta_2 \neq 0 \quad \text{or} \quad \delta_3 \neq 0.
\]
(11)

All the M-S tests introduced above are F-type tests based on the joint significance of the coefficient of the omitted factors. The only reliable conclusion one can draw on the basis of each of these M-S tests is whether there is evidence that Model 1 is misspecified in the direction being probed (see Spanos 1999; Mayo and Spanos 2004).

**See also** Hausman Tests; Specification; Specification Error
**Speculation**

Speculation is the acquisition of an asset exclusively for resale motivated solely by the anticipation of capital appreciation and gain. Most commonly, speculation occurs in anticipation of a price increase such that buying temporarily precedes selling as speculators temporarily hold title to (“go long in”) an asset. The possibility exists, however, of temporally reversing the trades in anticipation of a price decline through forward contracting. Here speculators would “short” an asset by agreeing to sell that to which they do not yet have title, planning the future acquisition of the anticipated cheaper asset in advance of the contracted delivery date. Speculation is similar to arbitrage insofar as arbitrage too involves the trade of commodities exclusively for capital gain. Arbitrageurs, however, trade across markets at a point in time so that opportunities for capital gains are much less risky than they are for speculators who conduct trades over time.

Any asset—as something that is capable of producing a stream of future material benefits—has the potential to be an object of speculation. Historically, real estate, precious metals, and financial instruments (stocks, bonds, currencies, and the like) have been the most common objects. At times, speculation in such assets has advanced at an especially feverish pace as Charles P. Kindleberger (2001) demonstrates in his discussion of the many historical episodes of speculative manias and their recoil in panics and market crashes.

**SPECULATION AND MARKET STABILITY**

There is considerable debate centered on whether speculation will act as a stabilizing or destabilizing market force. A long-standing dispute about the desirability of flexible versus fixed exchange rates has been periodically most vigorous, turning on precisely this question. Since the 1980s, researchers have debated the presence of destabilizing speculation in the form of a speculative bubble—as a process denoting movements in asset prices that cannot be justified on any reasonable economic grounds—as an explanation for observed volatility in equity markets.

The question of whether speculation will stabilize or destabilize a market hinges critically on the manner in which speculators form their expectations of future price changes. It was thought originally that if speculators based their expectations of capital gains on anticipated future changes in the conditions affecting the demand for or supply of an asset, then the act of speculation would even out price fluctuations over time. If instead speculators extrapolated from recent price trends, their actions would serve to increase the amplitude of price fluctuations rather than dampen them down. While such a characterization remains broadly accurate, subsequent research in rational expectations modeling has shown that speculation will be destabilizing even with some forms of forward-looking expectations of price changes.

Extreme volatility in currencies, stocks, and other financial markets in the mid- to late 1920s stimulated an effective challenge to the traditional classical way of thinking about speculation. Logic had previously held that speculation of any significance must be a stabilizing force; otherwise, if speculators were indeed a destabilizing force in the market, it would mean that speculators had worse foresight than average, their losses would then be greater than average, and so their existence would be short-lived. As Milton Friedman (1953) would later argue, “speculation can be destabilizing in general only if speculators on the average sell when the currency is low in price and buy when it is high” (p. 175).

For such reasoning to be sufficient grounds on which to deduce the absence of destabilizing speculation, several conditions must hold. Price expectations must be formed independently of the opinion of others, there must be a consistency between short-term and long-term anticipated gains, and the act of speculation itself must not alter the underlying economic value of the asset. If the future is known or equivalent to such, as in the case when one can define the full range of outcomes and associated probabilities, speculation is essentially an exercise in inter-tempo-

---

**Aris Spanos**
Speculation

...ral arbitrage, and the foregoing conditions could reasonably hold. The opportunity to speculate would be then a constructive market force wherein producers with greater risk aversion shift price risk to less risk-averse speculators. Otherwise, when the future is uncertain (as distinct from risky), the problem is much more complicated and the dichotomy between stabilizing and destabilizing speculation unclear.

Addressing the implications of true uncertainty in the formation of long-term expectations, John Maynard Keynes (1936) discusses the manner in which interdependent opinions may confuse and complicate the expectations formation process. In his famous beauty contest metaphor, Keynes likens investment to a beauty competition in which the winner is the one who most closely predicts the outcome that will be the opinion of the majority. The challenge for contestants then "is not a case of choosing those which, to the best of one's judgment, are really the prettiest, nor even those which average opinion genuinely thinks is the prettiest. We have reached the third degree where we devote our intelligences to anticipating what average opinion expects the average opinion to be" (p. 156). Keynes reserves the term speculations for this activity of forecasting psychology to underscore the important influence of social convention in the determination of outcomes and differentiates it from the "activity of forecasting prospective yield of assets over their whole life," which Keynes terms enterprise (p. 158).

Nicholas Kaldor (1939) carefully examines the implication of speculation for market stability by distinguishing between price stability and income stability. Even if speculation can be shown to stabilize prices, depending on the reactions of producers and elasticities of supply, the action may yield a greater instability in economic activity and incomes. Kaldor further argues that where the proportion of speculative transactions in the total is large, it may well be more profitable for individual speculators to focus on forecasting the psychology of other speculators rather than on the trend of nonspeculative elements. "Even if speculation as a whole is attended by a net loss, rather than net gain, this will not prove even in the long-run, self-corrective" (p. 2). Rudiger Dornbusch (1976) captures mathematically this inconsistency between short-term and long-term anticipated gains in a model of exchange rate "overshooting" driven by speculators with myopic perfect foresight.

Alongside the debate about the effects of speculation on the stability of currency markets is a parallel debate about the effects of speculation on the stability of equity markets. In a mathematical approach similar to that of Dornbusch, Robert P. Flood and Peter M. Garber (1980) examine a model of the speculative bubble in which forward-looking "rational" expectations may or may not motivate destabilizing speculation. The source of instability is a fundamental indeterminacy in the formal mathematical model, which is resolved in the literature by variously reducing the liquidity of the traded asset, introducing slow to adjust expectations, or imposing what is in effect a transversality condition that precludes by assumption anything but stability and convergence to a steady state. The steady state outcome is "efficient" in the sense that market prices fully and accurately reflect all relevant information about the future net income earning prospects of the assets discounted to the present. Viewed differently, the various "solutions" serve, in one way or another, to alter either the elasticity of expectations or the elasticity of speculative stocks, which together, as Kaldor had earlier argued, determine "the degree of price-stabilizing influence of speculation" (p. 9).

NONORTHODOX VIEWS

Where the orthodoxy focus on debating the stability implications of speculation in a probabilistic framework, heterodox economists concentrate on the implications for economic stability of speculation under conditions of true uncertainty. For Hyman Minsky (1982), financial fragility occurs in a world in which speculation in fixed assets is debt-financed and investors have both severely constrained foresight and limited memories of past distress. In his financial instability hypothesis, the evolving margins of safety between the streams of asset income in relation to the contemporaneous changes in debt service costs (rather than discounted present values) both characterize and explain the path of business fluctuations.

In a similar framework, Brenda Spotton Visano (2006) explores how the norm of speculation—as a collective dynamic—emerges when a revolutionary innovation shatters common understandings of the economic environment. The rate at which speculation in liquid financial assets related to the innovation becomes fashionable and spreads—thus sending asset prices spiraling upward—parallels the nonlinear, path-dependent diffusion course of the precipitating innovation itself. Because here the speculative activity materially affects an innovation’s potential, the material outcome is dependent on the collective assessment of that potential. In this case, what constitutes "excess" speculation is wholly unclear; in such environments, no criteria exist on which to base independent estimates of an asset’s fundamental value.

It follows that those who believe that speculation causes greater market volatility and misallocations of investment will advocate for some form of market intervention. Minsky recommends the presence of a lender of last resort in critical credit markets. Paul Davidson (1998) argues for a buffer stock mechanism in the control of a market maker. It is James Tobin’s proposal (1978) to levy
a tax on foreign currency transactions, however, that has attracted the greatest attention. As a means of raising the cost of speculative transactions, levying a “Tobin tax” would “throw some sand in the wheels of our excessively efficient international money markets” (p. 154)—a proposal that is similar in practice and in purpose to the long-standing policy of levying stamp duty on the buying and selling of British property and shares.

By contrast, those who believe that speculation is predominantly a stabilizing market influence continue to advocate for less market intervention. The theoretical and policy debates persist with no clear agreement in sight.

SPEECH ACT THEORY

Although the reflection on the performative dimension of language can arguably be traced back to the Sophists (Corax of Syracuse, Tisias, Gorgias, Protagoras, and Isocrates) of the fifth century BCE and their (lost) treatises on rhetoric and argumentation, it is John L. Austin (1911–1960) who usually is credited with being the first philosopher to systematically address this question. In his postmortem book titled How to Do Things with Words (1975), Austin showed that language can be used not only to describe states of affairs (as in This kitchen is very clean), but also to do things (in this case, to note that this kitchen is very clean). More specifically, Austin named the type of action a person performs in saying something an illocutionary act. For instance, in saying Come here! in specific contexts, I can be said to be giving my interlocutor an order, which is an illocutionary act. This act can also have consequences, such as my making my interlocutor come when I say Come here! Austin named this type of action a perlocutionary act, which is an act that comprises the intentional or nonintentional consequences that result from the illocutionary act.

Although Austin provided a detailed classification of speech acts, it is John R. Searle who developed the most thorough systematization of this theory of language (Searle 1969, 1979; Searle and Vanderveken 1985; Vanderveken 1990–1991). Searle identified five different types of illocutionary acts, which he called assertives (i.e., holding something to be true, as in This kitchen is very clean), commissives (i.e., committing oneself, as in I’ll be there), directives (i.e., getting someone to do something, as in Come here!), expressives (i.e., expressing a psychological state vis-à-vis something that was done previously, as in Sorry for stepping on your toes), and declarations (i.e., transforming the world by making it conform to the propositional content, as in I hereby declare that the session is open). Searle also identified what he called indirect speech acts, which correspond to the speech acts by which one says more than what is literally said. For instance, when I say Would you mind bringing me this chair? I am literally asking my interlocutor if she is willing to bring me a chair. Searle calls this type of literal speech act a secondary illocutionary act by which a primary illocutionary act (or indirect speech act) is performed. In this case, the indirect speech act consists of (politely) asking my interlocutor to bring me a chair.

Several critiques have, of course, been addressed to this theory. For instance, Stephen C. Levinson (1981,
1983), Marina Sbisà (1984, 1987, 2002), and Emanuel A. Schegloff (1988) deplore that the orthodox speech act theory fails to capture the complexity and sequential character of human interaction, which, at first sight, renders its use relatively sterile to people interested in the detailed study of interaction (but see Cooren 2000, 2005; Geis 1995; Jacobs 1989; Sanders 1987; van Rees 1992). Another critique, coming from Jacques Derrida (1988), consists of highlighting the iterable character of speech acts, that is, their capacity of being repeated (or iterated) in a potentially infinite number of contexts. According to Derrida, this iterability undermines the identification made by Searle between what a speaker/writer means and the type of speech acts he or she produces (a monologism also denounced by Sbisà). According to this perspective, what the producer of a given speech act means is something that is conventionally reconstructed a posteriori by the participants and not something that defines a priori what a given speech act will count as. This reflection paves the way for a model of speech acts that would take into account the speech agency of things as diverse as documents, as in This announcement invites a bid for the construction of their building, where we attribute to a text the action of inviting; or spoken words, as in His words blessed their union, where the focus is on the agency of pronounced words (Cooren 2004).

**SPENCER, HERBERT 1820–1903**

Herbert Spencer (1820–1903) was a nineteenth-century English social philosopher who sought to explain all domains of the universe in terms of some “cardinal” or “first principles” of evolution. He termed his approach “synthetic philosophy,” and before he was done he wrote treatises on ethics (1851, 1892–1898), psychology (1855), biology (1864–1867), and, eventually, sociology (1874–1896). He also wrote a major work on methodology in the social sciences (1873) that was far superior to anything written at the time, and he commissioned the
largest collection of data by a sociologist on human societies in the sixteen volumes of his *Descriptive Sociology* (under various authors from 1873 to 1934). This latter project served as the inspiration for the Human Relations Area Files initiated by George P. Murdock, which sought to categorize and quantify qualitative data from ethnographic studies of societies.

Spencer coined the phrase “survival of the fittest” almost a decade before the English naturalist Charles Darwin’s analysis of natural selection appeared; in many ways, modern views of Spencer are colored by this phrase and the social advocacy it contains. In fact, Spencer’s arguments about “ethics” taint present-day perceptions of his work because by today’s political standards they appear conservative, although they were liberal in Spencer’s time. Perhaps the most unfortunate impression of Spencer’s sociology is its association with the rise of social Darwinism and the eugenics movement with Spencer’s advocacy. Both of these movements gained traction long after Spencer’s death; thus, Spencer cannot be seen as a key player in what they advocated.

Spencer’s ideas were, however, used by some key advocates of social Darwinism or eugenics. For example, in his key work, *The Genetical Theory of Natural Selection* (1930), the English evolutionary biologist Ronald A. Fisher significantly advanced the field of genetics in the first half of the book, but used Spencer’s ideas to promote a version of eugenics in the second half. The same is true for social Darwinists who often invoked Spencer’s (and, more often, Darwin’s) name to legitimate their advocacy that the natural competition among individuals should be allowed to play itself out within societies just as it does in the natural world. Spencer used the phrase “survival of the fittest” most often within sociology to address the topic of how war had historically allowed societies to evolve, with the more organized and fit society generally winning a war and advancing the level of organization of human societies. Still, he did advocate that competition among individuals and collective actors within societies should go unregulated, letting the more fit survive. In reading Spencer’s more scholarly works, however, and particularly his sociology, there is very little of this latter form of advocacy. And yet, in the twenty-first century Spencer’s reputation is often tied to discredited intellectual movements. Spencer was an ideologue when he wrote on ethnics, to be sure, but he was also a scientist and scholar whose works have not received the attention that they deserve because of the prejudices against his ideological moments.

Thus, Spencer was more than an ideologue. His collected works comprise one of the most comprehensive collections of scholarship ever produced in the social sciences. His sociological works, which came late in his career, are perhaps his most important because they drew upon the vast body of data assembled by scholars under his financial sponsorship and patronage into the volumes of *Descriptive Sociology*. The Principles of Sociology* (1874–1896) presents a functional approach, emphasizing that the evolution of human societies is the result of population pressures for structural and cultural differentiation around three main axes: operation (functional needs for production and reproduction), regulation (needs to consolidate power), and distribution (needs to create infrastructures and exchange systems for moving people, resources, and information about a society). What scholars often overlook in this analysis is the emphasis on power. Most of *The Principles of Sociology* examines the effects of concentrated power on increasing inequality which, in turn, shapes the structure of key institutional systems: economy, kinship, religion, and politics. He also developed a theory of microdynamics, revolving around ceremony under varying levels of concentrated power and inequality.

In *The Principles of Sociology*, Spencer presented a geopolitical theory of human evolution, emphasizing the effects of inter-societal conflict on social complexity and on concentrated power. War was the main referent for the phrase “survival of the fittest” in Spencer’s sociology; with this idea, he documented that, in general, the more complex and better organized society will generally defeat the less complex and less organized society. With conquest, then, comes the successive ratcheting up of the level of societal complexity. However, war forces the centralization of power that, in turn, increases the level of inequality. Inequalities pose internal threats that, ironically, force more centralization of power to manage them—thereby escalating inequality in a cycle that ultimately leads to societal dissolution or deevolution. Still, despite this cyclical dynamic, societies have become larger and more differentiated over the long course of history. When differentiation of societies has produced free markets as the main mechanism for distribution, Spencer felt that war and its effects on centralization of power and inequalities in all institutional spheres work against further societal evolution. War and concentrated power create what in the 2000s is termed the “military-industrial complex” that deprives the economy of capital and limits innovation, thus serving as a drag on societal evolution.

Spencer was the most-read social philosopher of the nineteenth century, yet modern social scientists rarely consult his work because it is associated with discredited intellectual and social movements in which Spencer was not an active participant. In many ways, this state of affairs is a bit unfair to Spencer’s legacy but it is also understandable given the extremes to which Spencer’s ideas were taken by later ideologues. Still, Spencer’s collective works contain many useful insights that can still serve social science (for a detailed analysis of Spencer’s sociology...
see Turner 1985; for a complete primary and robust secondary bibliography on Spencer’s work see Perrin 1993).

**SPIRITUALITY**

The term *spirituality* is at the center of much debate on the shape and meaning of religion in the modern, or postmodern, world. Yet the term defies an easy or singular definition—it is an “attitude or principle that inspires, animates, or pervades thought, feeling, or action,” to quote *Random House Webster’s Unabridged Dictionary* (2nd ed., 1997). It is worthy of note that both the verbs and the spheres of activity to which the verbs point in this definition vary. Beyond spirituality’s broad sweep in thought, feeling, and practice, all pointing to the inner, subjective world of religion, spirituality is also viewed as having emerged, as Ursula King points out, as “a general code word for the search of direction, purpose, and meaning related to the deepest dimension of human existence” and is thus “no longer exclusively based on an a priori theological standpoint, but is rooted in a search, in experimentation, questioning and exploring” (1998, p. 96).

Writing more than a century ago, the American psychologist William James (1842–1910) privileged this inner space in his classic definition of religion as “the feelings, acts, and experiences of individual men in their solitude, so far as they apprehend themselves to stand in relation to whatever they may consider the divine.” James distinguished this personal, experiential element within religion from the “theologies, philosophies, and ecclesiastical organizations [that] may secondarily grow up” around the experience ([1902] 1985, p. 31).

Viewing religion broadly as a transcendent and often transforming experience, he left open the form of the experience itself and the devotional object at the center of that experience. Spirituality is thus the primary and motivating quality of religion—“whether the religion in question,” writes Catherine L. Albanese commenting not specifically on, but in keeping with James’s outlook, “is organized or of movement status or mostly individual; and whether it involves God, or other-than-human guides and spirits, or the center of the Self, or an almighty Nature, or an ideal held to be worth living or dying for” (2001, p. 11).

Spirituality thrives in the context of a living religious tradition; indeed, the latter’s constituent elements of symbol, doctrine, myth, ritual, text, and story all shape an experiential religious world. Belief and practice embedded within tradition “keep alive” a sense of transcendence, sacrality, and ultimacy. Put differently, religion is a symbolic and linguistic system that by its nature is powerfully evocative—it triggers experiences and emotions and at the cognitive level defines a meaningful universe including proper strategies of action. Encoded signs and symbols are the means by which experiences not only are generated but are described, even recognized and labeled, as religious. Historically, the major world religious traditions have relied upon symbolic forms for breaking outside of the profane world and into an alternative reality known only through its ecstatic qualities and interpretive frames. Even within contemporary, more secular social settings, research suggests that those persons most involved in their religious traditions are more likely to report having strong religious experiences (Yamane and Polzer 1994, pp. 1–25).

More appropriately, we should speak of spiritualities—emphasizing the plural—since they vary by tradition and social and personal circumstance. Monotheistic,
and typically highly monarchical religious traditions such as Christianity, Judaism, and Islam image God as a distant powerful being, as a male, kinglike lawmaker and judge, and locate the central human problem as one of sin and guilt as measured against divine standards. Emphasis is upon what Marcus J. Borg describes as a “performance model” of spiritual practice, of trying to meet the requirements God expects (1997, pp. 62–71). Hence the dominant God is somewhat more distant as traditionally conceived. But in the many Hindu and Buddhist traditions with their numerous gods, male and female, or no god, stress is upon devotion and meditation in quest of inner peace, joy, and liberation. There are many spiritual paths toward a higher consciousness through the cultivation of experiences of connection, belonging, wholeness, and selflessness. Eastern spiritual diversity thus stands out in contrast to the more monotheistic Western styles.

Religious symbols, belief, and community generate spiritual energy, but social factors shape the form the spiritual dynamic will take. As Max Weber (1864–1920) observed, the spiritual styles and theodicies for ruling elites differ markedly from those who are either weak and powerless or socially mobile. The spiritual dynamics of elites typically focus more upon the blessedness and naturalness of the existing order; the powerless on otherworldly rewards that should come in the next life; and the socially mobile on the importance of getting ahead and doing well. Metaphysical spiritualities acknowledge these same features of the natural order but usually without full-blown justifications for dominance. Minorities are often, though not always, characterized by otherworldly spirituality. At times they are motivated spiritually by religiously inspired ethical ideals to engage in struggles against oppression and inequality, an obvious example being the civil rights movement led by the Reverend Martin Luther King Jr. (1929–1968). Rooted in the African American Christian experience, King exposed the gap between ethical ideals and social injustice; addressing a deep psychological dissonance between ideals and practice, he thereby mounted a “spiritual protest” without having to resort to the use of violence as a means of bringing about constructive social change.

In the contemporary world, spirituality takes increasingly diverse forms in response to changing social and cultural realities. One emerging pattern is described as post-traditional, characterized by the searching and experimenting Ursula King speaks of. Individuals acting with a great degree of autonomy explore spiritual truths from many sources, mixing and matching elements to their own choice. High levels of exposure to religious diversity contribute as well to a mixing of the codes. Cross-national research in Western countries suggests that this pattern holds broadly for the post–World War II (1939–1945) generation (Roof et al. 1995), and especially so in the United States. Seeker-oriented spirituality is compatible with life in modern, rapidly paced societies. Also, in these settings, ties to faith traditions are often weak. Social and religious conditions thus make for a thriving “spiritual marketplace” where innovative entrepreneurs compete with one another in defining spiritual needs and in supplying meaning and practice—all intended to assist the individual in his or her spiritual journey. Drawing upon the spiritual resources available to them, both within and outside of organized religion, people assume a considerable amount of self-direction in cultivating their spiritual lives.

A distinction between spiritual and religious is becoming more commonplace in advanced modern societies. Within the United States, for example, the number of people claiming to be “spiritual but not religious” is estimated variously (but with differing empirical measures) as 14 percent (Roof 1999) and 31 percent (Wuthnow 2005) of the adult population. To be religious implies faith in God or the divine, participation in institutionally based practices, and respect for the teachings of a tradition; to be spiritual puts emphasis upon the experience of connectedness, relationship, or oneness with God/Christ/a higher power/the sacred/nature and appreciation for personal growth and inner awareness in one’s life journey. Various empirical measures of self-rated religiousness and spirituality are increasingly used by social scientists as a means of taping these differing responses. Self-rated religiousness is related to attendance at religious services and orthodox belief, whereas self-rated spirituality is associated with mystical experiences and New Age beliefs and practices, particularly among those with higher levels of education and income. An expanding body of research links these two to a broad range of social, psychological, and behavioral correlates, particularly in areas of psychotherapy, child-rearing philosophy, and lifestyle research (see Zinnbauer et al. 1997).

Research suggests that the vast majority of those claiming to be religious are also spiritual—indeed, the spiritual lies at the core of religious life. But if the post-traditional spiritual quests described above represent shifting styles of individual religious expression, a second pattern might be called retraditionalizing, or the deliberate cultivation of spiritual meaning through committed religious life and practice. Described as engaged spirituality, this effort is deeply grounded within congregational religious life and thus is less individualistic in style, and seeks to combine spiritual depth with social concern and responsibility (Wuthnow 1998; Stanczak 2006). A third, quite different pattern is the neotraditional response, or the attempt at reconstructing and enforcing older religious beliefs and values throughout a sociopolitical order. Protesting the erasions of modernity, efforts such as these typically arise in close alignment with political ideologies and mass movements, as with the mobilization of the
Religious Right in the United States or the rise of radical Islamic militants in various parts of the world. Spirituality of this kind arises out of a remythologizing of narratives of God, people, and nationality in search of religious certainty and a more secure moral universe.

SPOCK, BENJAMIN

1903–1998

Benjamin Spock was, for a generation, the canonical authority in America on the raising of children. Even after Spock passed the apogee of his influence, he continued to be the point of reference for almost all writers on the subject for the next forty years and into the early twenty-first century. By almost any standard Spock was the most important American author of child-rearing advice of the twentieth century. His principal work, Baby and Child Care, went through seven editions, was translated into thirty-eight languages, and sold more than fifty million copies around the world. Aside from the Bible, it was the best-selling book of the twentieth century in America.

THE EARLY YEARS

Spock was born in New Haven, Connecticut, the son of a successful corporate lawyer. He graduated from Yale University, won a gold medal as an oarsman at the 1924 Olympics, and went to medical school at Columbia University. In the 1930s Spock studied at the New York Psychoanalytic Institute. He was the first psychoanalytically trained pediatrician in New York, where he maintained a private practice from 1933 to 1943.

Spock’s Park Avenue practice brought him overtures from publishers, who pressed him to write a book setting forth his distinctive combination of pediatrics and child psychology. In 1946 he did. The first edition of The Common Sense Book of Baby and Child Care began, as did all subsequent editions: “Trust yourself. You know more than you think you do.” It invited mothers to indulge their own impulses and their children’s, assuring them on the basis of the latest scientific studies that it was safe to do so. In the process, the book overturned the expertise of the previous generation and authorized mothers to express their “natural” feelings toward their children.

Earlier advice, embodied in the convergence of the psychologist John Watson’s Psychological Care of Infant and Child and the U.S. government’s Infant Care pamphlets of the 1920s and 1930s, warned against parental deviation from rigid disciplinary schedules and undue display of fondness or physical affection. Spock urged spontaneity, warmth, and a fair measure of fun for parents and children alike. He insisted that there were no infallible rules and that each child had to be treated as a distinct individual.

A CHILD-CENTERED APPROACH

Baby and Child Care seemed predicated on an unprecedented child-centeredness that celebrated instinct in youngsters and their mothers as well. After decades during which parents had been told they would spoil the child disastrously if they yielded to the child’s demands, Spock told parents they could trust the child’s desires and their own. “What you instinctively feel like doing is best,” he promised his readers, in deliberate defiance of Watson. If you “feel like comforting the child, do it.” The very feeling would make it “natural and right.”
Spock found parables of the reliability of desire in what was at the time the most current research on sleeping and eating. Those studies showed that infants stabilized a bedtime schedule on their own, without parental coercion, if given a little time. The studies demonstrated that somewhat older children worked out a feeding routine on their own, if they were indulged while they came to it. Older children even chose a balanced diet once past the first rush to sweets. Afforded free run of a smorgasbord, children pigged out for a few days on candy, cake, and ice cream but then of their own volition turned to proteins, greens, and grains. It turned out that, as Spock put it, the child “knows a lot.” Parents could give in to their child “without worrying about the consequences,” hard though it might be for them “to have this kind of confidence in [the child’s] appetites.” Modern mothers and fathers were “lucky” to be able to let go and be “natural.”

Impulse—of both the child and the parents—could be safely followed. Spontaneous inclination was a virtue, deliberate control a vice. A mother angry at her child would do better to express her anger at once. Waiting until she calmed down and came to conscious mastery would be “grim” and “unnatural.”

Conservative critics later complained that Spock promoted what they called permissive child rearing. In one of the earliest expressions of the "culture wars" that marked the last quarter of the twentieth century, critics held Spock responsible for the counterculture and the collapse of conventional morality. On their face, such charges were difficult to sustain. Spock never counseled permissiveness and soon enough advised against it. He simply had no stake in permissiveness per se. When critics of the 1946 edition assailed what they took to be Spock's undue indulgence of the child, Spock rewrote the permissive passages without a pang in the second edition. As Spock said in that revised version and in every revision that came after, the issue was not intrinsically important. Both strictness and permissiveness would work for “goodhearted” parents, neither for “insecure” ones. The only matter of any real moment was “the spirit that the parent [put] into managing the child.”

Discipline and indulgence were not, for Spock, at odds. He trained as a psychoanalyst, but he never permitted Sigmund Freud’s (1856–1939) tragic vision to inflect his advice. Civilization, in Spock’s view, did not entail discontents. Conflict was not in the nature of things. Antagonism only appeared when parents mismanaged.

Spock’s essential endeavor was to keep parents from activating the infantile ego. His deepest concern was to prevent pitched battles of will between mother and child. He resorted to permissiveness only as a tactic—one among several—in a larger strategy of conflict management. It was never a principle, only a ploy, driven by fear of the fallout of contention.

AN ACTIVIST LIFE
But if Spock did not espouse opposition in his pediatrics, he embraced it in his politics. Even before the war in Vietnam, he warned against the dangers of nuclear testing and served as cochairman of the National Committee for a Sane Nuclear Policy. He was a vocal opponent of the war, helped lead the march on the Pentagon in 1967, and was convicted and sentenced to jail for conspiracy to aid draft resisters in 1968. (His conviction was reversed on appeal.) He ran for president in 1972 as the candidate of the People’s Party and continued as an activist long after. Past the age of seventy, Spock was arrested for protesting against a nuclear power plant in New Hampshire, budget cuts at the White House, and nuclear weapons at the Pentagon. Past eighty, Spock still gave as many as a hundred talks a year on the nuclear arms race.

Spock’s child-rearing advice changed as his political views and American family life evolved. In successive editions of Baby and Child Care, he made a place for fathers as well as mothers in child care, allowed new gender roles for boys and girls, acknowledged divorce and single parenting, and explicitly urged vegetarianism on his readers.

But in essentials Spock’s advice never changed. He always aimed to write a guide for living more than a medical reference book. He always challenged conventional notions of normality and sought to alleviate anxiety, in parents and children alike. He always offered reassurance in the down-to-earth manner in which he set forth his advice. He had a genius for popularization. No one ever explained Freud better in everyday language. No one ever wrote better gender-neutral prose.

Even as Spock set himself in militant antagonism to the status quo in politics, he endeavored to help parents accommodate their children to fit in the society and the economy the children would encounter. However inadvertently, he pushed mothers and fathers to prepare children for the corporate bureaucracies in which they would make their careers. He emphasized the cooperativeness and congeniality that organizational life demands. He held that parents “owe it to the child to make him likeable” and that they had to make the child be like others to be likable. He never did reconcile his dissident politics and his conformist child rearing.

SPORTS

Sport is a social phenomenon that deeply permeates societies throughout the world. Millions of people view, participate in, or discuss sporting events on a near daily basis. Further, sport has become a multibillion-dollar industry that employs thousands of people. As sport has become more pervasive and as the size and magnitude of the sport industry has grown, it has increasingly come under the scrutiny of sociological researchers. The purpose of this entry is to overview some of the major issues and insights developed from a sociological analysis of sport. This overview is categorized into two sections. First is a discussion of sociological studies of sports as an institution that has significant implications for the lives of participants, their families, and the communities in which they live. The second category of studies views sports as a microcosm of society, which provides a fertile field to test sociological theory and gain insights about society. This entry continues with an overview of both of these research agendas.

SPORT AS A SOCIAL INSTITUTION

Research on sports as a social institution has been guided by two very different theoretical perspectives. On the one hand, researchers using a systems model, largely derived from functional theory, tend to see sport as an institution that contributes to society by reinforcing major cultural values such as success, achievement, competition, work, and cooperation, and also increases community or school unity. Other sociologists examine sport from a conflict perspective where it is viewed as an "opiate of the masses" (Coakley 2001; Eitzen 2001).

Sport as an Inspiration: The Functional Perspective

Numerous studies have been conducted that seek to determine the consequences of sports involvement for participants. Prominent among this research are studies seeking to understand the relationship between involvement in sports during childhood and adolescence and a variety of simultaneous and adult outcomes. While a variety of possible outcomes have been explored, two representative examples of this line of research are described herein. These examples include the relationship between sports participation and adult income and sports participation and the sexual behavior of teenage females.

A number of researchers have empirically explored the relationship between sports participation and adult income. These studies have consistently found that individuals who participate in youth or high school athletics generally have adult earnings that are higher than individuals who do not participate in sports. For the most part, these relationships remain significant when factors such as race, parents' socioeconomic status, and parents' educational attainment are statistically controlled.

Similarly, researchers such as Tamela McNulty Eitle and David J. Eitle (2002) have determined that sports participation is strongly associated with the sexual behavior of adolescent females. This research found that adolescent females who play sports are less likely to have ever had sexual intercourse (Miller et al. 1999), have an older age of onset of sexual activity (Brown et al. 1997; Miller et al. 1998), and have higher rates of contraceptive use (Miller et al. 1999). Even after adolescence, Eitle and Eitle found that those who participated in sports were less likely to become pregnant outside of marriage and to have had fewer lifetime sex partners.

Researchers have attempted to explain why participation in athletics tends to have these positive outcomes. Explanations include physical appearance; it is argued that being stronger and healthier provides advantages in both athletic participation and the work force. Christopher Shilling's 1992 findings maintain that the physical capital accrued through sports participation is convertible to other forms of advantage in other areas of life. Researchers James Curtis and colleagues argued in their 2003 work that athletes gain self-confidence, which leads to better choices; they learn important interpersonal skills, and athletic involvement provides visibility and social networks.
Sport as an Opiate: The Conflict Perspective

Some scholars argue that sport is an institution that provides the illusion that success can be achieved by anyone with talent and who is willing to work hard. As a result, sport is one of the institutions that allows deep and persistent patterns of prejudice, discrimination, and inequality to continue. Thus, because a few minority athletes have become extremely famous and wealthy, society is lulled into thinking that prejudice, discrimination, and racism are largely problems of the past. In addition, some maintain that sport is a powerful reinforcer of a racist ideology. For example, African Americans are typically represented as being athletically superior. Unfortunately, concomitant is the belief that they are mentally inferior. Thus from an observation of sport one is given the impression that minority athletes succeed because of physical prowess, while white athletes succeed through perseverance, hard work, and intelligence. To show that this racist ideology persists into the twenty-first century, in 2004 J. R. Woodward examined the sports guides dedicated to critiquing collegiate players eligible for the annual National Football League draft. He found that African American players were more likely than white players of their same position to be described in physical rather than mental terms.

Also from the conflict perspective, sport can be viewed as a tool used by the advantaged to help them maintain their privileged positions. In his book Beer and Circus (2000), Murray Sperber discussed how modern college sports are used as an “opiate of the masses.” He noted that since the mid-twentieth century the cost of college education at large state universities has increased dramatically. At the same time the quality of that education has diminished as class sizes have significantly increased and a much higher proportion of the classes are taught by graduate students or part-time faculty. Sperber argued that to distract students from the fact that they are paying more and getting less, colleges have placed greater emphasis on sports. Thus, rather than demanding academic change, students focus on the upcoming football or basketball game. Meanwhile, so-called “student-athletes” are recruited to fill the stadium and keep alumni donations flowing. The exploitation of these student-athletes is evident as the vast majority will not have the benefits of a career in professional sports and are placed in circumstances where academic success is unlikely. When their eligibility has expired, these former student-athletes leave college, often without a degree and lacking the skills necessary for success in life outside of athletics. Similarly, Douglas E. Foley’s 1994 ethnographic study of a Texas high school describes how high school football is an agent of socialization that reinforces existing patterns of race and gender inequality.

Professional sport represents the epitome of capitalism, and much can be learned about labor relations in general by watching the conflict between professional sports team owners and athletes. The actions of professional athletes closely parallel the actions of other workers as they seek higher wages and better working conditions. Like other workers, professional athletes have sought redress in the courts and they have formed unions and organized strikes. At the same time, owners attempt to keep wages low so their profits will be greater.

In addition, much can be learned about race relations in the United States from sports as circumstances in sport generally reflect circumstances in the remainder of society. While sport appears on the surface to be a very meritocratic institution, where participants are rewarded strictly on the basis of their accomplishments, a careful examination reveals extensive patterns of inequality. For example, while minority athletes are visible and numerous in sports such as basketball and football, they are underrepresented in many other sports. Further, minorities are underrepresented in positions of power in virtually all sports. The owner of nearly every professional sports franchise is white, minorities are rare in the upper management of sports, and most coaches are white. For example, during the 2005 college football season, only 3 of the 117 teams playing Division I football had a minority head coach. Given these circumstances, it is not surprising that minority assistant college football coaches perceived less career-related opportunity, were less satisfied with their careers, and had greater occupational turnover expectations than their white counterparts.

Among players, sociologists have detected a phenomenon called “stacking.” Racial stacking is the over- or underrepresentation of players of certain races in particular positions in team sports. For example, quarterbacks in football and pitchers and catchers in baseball have traditionally been white, while running backs and defensive backs in football and outfielders in baseball are much more likely to be minority. Again, this pattern reinforces a racist ideology as white athletes dominate positions of power where mental skills and leadership are essential.
while minority athletes dominate positions where pure athletic skill is more critical.

There are also extensive differences by race in the sports that individuals play. In 2003 Pat Goldsmith conducted a study of the racial patterns of school sports participation and used these differences as a forum to test economic and cultural theories to explain these differences. Economic or structural theories predict that differences by race exist because of economic differences across races. Cultural or racial theories would predict that differences would exist even when socioeconomic status was equal. He found that economic theories best predict the sports that whites play, while cultural theories best predict the sports that blacks play.

It should also be noted that similar patterns of inequality in sports are found relative to gender. In college and high school, female sports generally receive only a minority of the athletic budget and the coaches of female teams have significantly lower salaries. In sum, the sociology of sport is a new and dynamic subdiscipline with the potential for significant insights about sociological theory and about societies in general.

SPORTS INDUSTRY

Athletic activities have long been part of all societies, but it was not until the early twentieth century that professional team sports began to develop. Since then, the top levels of basketball, football (soccer in North America), baseball, hockey, and North American football have
become widely popular professional activities that have attracted the attention of economists.

While professional sports grew in the first half of the twentieth century, a major turning point came in the 1960s when lucrative television contracts began to greatly increase team revenues. Revenues were no longer limited by the number of seats in the stadium or arena. Players’ salaries later increased rapidly. Economists’ interest in the sports sector did not begin in earnest until the 1990s, largely as a result of the increased involvement of the public sector in financing professional sports facilities in the United States. The first economics journal in the field, the *Journal of Sports Economics*, began publication in 2000.

**GROWTH OF PUBLIC FUNDING**

The policy issue that has attracted the most attention from economists is the growth of public funding of stadiums and arenas in the United States, funding that is based on the proposition that professional teams have a significant economic impact on a city.

The sports industries argue that teams raise incomes and employment in host cities and that publicly funded facilities, and perhaps tax concessions, are a good investment for an urban area. If these benefits are the carrot, the stick is the threat to move a team to a more hospitable city. To make this a credible threat, leagues typically keep in reserve at least one city that is anxious to host a team. As a result, many cities have provided subsidized facilities, with price tags in the hundreds of millions of dollars.

Economists have undertaken many studies of whether these subsidies are warranted. There is little difference in their results, which conclude that teams have either a slightly negative or no discernable impact on a city’s economy. Rodney D. Fort discussed some of these studies in his book *Sports Economics* (2006).

A number of factors explain these findings. Perhaps the most important is that team-related spending by local residents is still spent, but on other goods and services, in the absence of a local team. In addition, professional sports as a tourist attraction are overstated; while visitors attend games, they usually come to the city for other reasons and enjoy games while they are in town. Finally, much of a team’s revenue is spent outside its city, both for away games and for the earnings of players who live elsewhere in the off-season.

**PLAYER MARKETS**

A second major area of interest to economists is the analysis of the markets for players. These markets provide examples of shifting market structures and changing claims to income. For many years, teams held monopolistic powers, the power that comes to a single buyer, in the market for players. This power came from player drafts and reserve clauses.

The player draft is a system in which teams in a league select (“draft”) incoming players in an ordered fashion, usually in reverse order of finish in the last season: the team that finishes last gets the first draft choice for the next year. A player may sign only with the team that drafts him, and that rule applies even when a team trades or sells a draft choice to another team.

The reserve clause, which originated in professional baseball in 1877, bound a player to the team with which he signed his first contract, usually the team that drafted him. While the team had the power to trade the player or to sell his contract, the player was not able to sign with another team even when his contract expired. As the only buyer, a team held complete monopsony power and was thus able to keep salaries low.

Leagues argued that these restrictions on player movement improved competitive balance across teams. In fact, however, economic markets still functioned. Teams traded both draft choices and players. As Fort pointed out in *Sports Economics*, there is no statistically significant difference in competitive balance before and after draft systems were in place in the National Football League and in Major League Baseball. Rich, winning teams have tended to buy good players and maintain their winning ways.

Teams’ monopsony powers were reduced by the growth of player unions in the 1960s and 1970s. There have been player strikes and owner lockouts in several sports. As a result, the markets for players have changed.

Reserve clauses began to break down in baseball in the late 1970s, and other sports followed. While player drafts still operate, reserve clauses bind a player to a team for a limited number of years. Players now become free agents after several years in the league and are able to change teams and to negotiate their own contracts.

As a result, salaries are much higher than they once were. Michael Leeds and Peter Von Allmen cited examples in *The Economics of Sports* (2005). Average annual salaries in the United States in 2002 ranged from a low of $1.3 million in the National Football League to a high of $4.5 million in the National Basketball Association. At the same time in Europe, ordinary soccer players earned from $600,000 to over $1 million dollars annually, plus bonuses. Star players in all sports earn far more, as they attract more fans and increase box office and television revenues. It is not clear whether these salary levels will continue in all sports, as the 2004 to 2005 season-long lockout in the National Hockey League has resulted in team salary caps.
SCANDALS

Two problems continue to plague major league sports, despite the efforts of many organizations. First, there are scandals arising from the use of performance-enhancing drugs; in 2006 alone, for example, there were widespread doping allegations in major league baseball and in the Tour de France cycling race. Doping scandals have led to questions regarding the legitimacy of records set by players or teams later found to have been using performance-enhancing drugs. Second, and more infrequently, there is game fixing, usually associated with gambling. In 2006, for example, a widespread game fixing scandal arose in football (soccer) in Italy, involving several of the country’s top-level teams.

There are similar problems in amateur sports, where success may bring present or future financial rewards. In some sports it is lucrative advertising contracts for “amateur” athletes. In others, such as American football, universities are training grounds for professional athletes, and it is the promise of future benefits that tempts some players to use performance-enhancing drugs.

Politics plays a key role in international sports. At various times, countries have boycotted the Olympic Games, as in the Moscow Games of 1980. Votes to award the Olympic Games to a city are often a very political matter, sometimes associated with charges of bribery, as in the case of the 2002 Winter Games awarded to Salt Lake City, Utah.

These problems aside, markets in sports industries operate as understood by economic theory. Each team in a professional sport has some monopoly power as the only seller of the sport in its home city. A team also has some monopsony power as one of a small number of buyers of player talent. After a few years, ordinary players have market power in the sale of their services, augmented by union contracts. A very good player has considerable power as his marginal revenue product exceeds that of other players. But all this likely matters little to fans, the final purchasers of the industries’ outputs. Fans, after all, do not cheer for markets, they cheer for their home team.

SPOT MARKET

The point in time when a buyer and a seller agree to the terms of a transaction (the contract date) need not be the same as the point in time when the transaction occurs (the execution date). For example, on January 1 a buyer and a seller can agree on the terms of a transaction to be conducted on February 1. When the buyer and the seller agree to the terms of the transaction prior to the execution of the terms of the transaction, it is said that the transaction occurs on a futures or forward basis (wherein the distinction between the two involves specific terms as to how the transaction is to be handled). The agreed price is called a futures or forward price. Alternatively on January 1 a buyer and a seller can agree on the terms of a transaction to be conducted immediately. When the buyer and the seller agree to the terms of the transaction at the same time that the transaction is executed, it is said that the transaction occurred on a spot basis. The agreed price is called a spot price. Most consumer transactions, with the exceptions of major transactions such as home purchases, are conducted on spot bases.

The spot market is a formal market for buying and selling securities and commodities on a spot basis. In practice, while the physical transfer of the securities or commodities (called settlement) may take a day or more, for legal and accounting purposes the transaction is assumed to have occurred instantaneously. In a futures or forward market, it is not the securities and commodities that are sold but rather contracts for the purchase or sale of securities and commodities at some future date. The purpose of the futures or forward markets is to enable the buyers and the sellers to mitigate the risk of future price fluctuations by locking in the price prior to the transaction occurring. Forward and futures markets evolved as a means of transacting business when the physical delivery of the product was forced to take place in the future. Examples include selling a crop prior to the harvest and buying a product that must be shipped from overseas. If sellers seek to mitigate risk, then they will be willing to sell their products on a forward or futures basis for less than they would otherwise sell them for on the spot market. If buyers seek to mitigate risk, then they will be willing to pay more on a forward or futures basis than they would be willing to pay on a spot basis.

The purchase of a security on a spot market with the intent of reselling the security at a later date on a spot market resale at a higher price is called speculation; the purchase of a security on a spot market with the intent simultaneously to sell the security at a higher price on a different spot market is called arbitrage. For example, in arbitrage one might purchase €1,000 at a price of $1.25 per euro on the New York spot market and simultaneously sell the €1,000 at a price of $1.26 per euro on the
London spot market, making a profit of $10. In speculation one might purchase €1,000 at a price of $1.25 per euro on January 1 and sell the €1,000 at a price of $1.26 per euro on February 1, making a profit of $10.

Arbitrageurs (those who conduct arbitrage) serve an important role in financial markets. By constantly looking for and exploiting pricing discrepancies, arbitrageurs force prices in different markets to equate. For example, if euros sell for a higher price on London markets than on New York markets, arbitrageurs will step into the market, buying up euros on the New York spot market and simultaneously selling them on the London spot market. This increase in the demand for euros in New York causes an increase in the price of euros on the New York market. Simultaneously the increase in the supply of euros in London causes a decrease in the price of euros on the London market. The arbitrage will continue, and the prices will continue to move until the prices on the two spot markets become equal. (In practice the prices will not become exactly equal due to small costs for conducting the transactions.) At that point there is no further incentive to arbitrage, and so the arbitrage stops. There are enough people attempting arbitrage and financial markets are efficient enough that computers are usually required to conduct arbitrage because price discrepancies, when they occur, are quickly arbitrated away. The benefit that arbitrageurs play is to alleviate people seeking to buy currency on spot markets from having to compare prices across many markets. Virtually all the time (non-arbitrage) buyers and sellers are guaranteed that the price they see on one spot market is identical to the prices they would find on all other spot markets.

SPOT PRICES

SEE Spot Market.
interest rate); when the yield curve is downward-sloping (referred to as an inverted yield curve), the term spread is negative (the long-term interest rate is below the short-term interest rate); and when the yield curve is flat, the term spread is zero (short- and long-term interest rates are the same). Frederic Mishkin and Apostolos Serletis, in chapter 6 of their 2007 study, discuss the yield curve and the term structure of interest rates.

Early investigations into the risk and term structure of interest rates looked at whether the slope of the yield curve—the spread between long- and short-term interest rates—helps predict future short-term interest rates. Studies, such as those by Robert Shiller and colleagues (1983) and Gregory Mankiw and Lawrence Summers (1984), found that the yield curve does not always help predict future short-term interest rates. Subsequent research, however, using better testing procedures, supports a different view. Studies by Eugene Fama (1984) and John Campbell and Shiller (1987, 1991), for example, show that the spread between long- and short-term interest rates contains useful information about future interest rates over the short run and the long run, but not over the intermediate term.

The slope of the yield curve also contains information about overall economic conditions. In fact, an extensive literature documents the usefulness of the yield curve in predicting future economic activity, such as Arturo Estrella and Gikas Hardouvelis’s 1991 study and Estrella and Mishkin’s 1996 and 1998 studies. However, twenty-first-century monetary policy procedures and globalization may be causing this relationship to loosen. In particular, the Federal Open Market Committee in the United States raised the target federal funds rate in seventeen consecutive meetings from June 2004 to July 2006, from 1 percent to 5.25 percent, but long-term interest rates in the United States declined for most of this period. In fact, long-term interest rates around the world have recently exhibited similar declines despite steady increases in short-term interest rates.

As Tao Wu argues in his 2006 study, the reason long-term interest rates have not been responding during the worldwide round of monetary tightening since the turn of the century is the adoption of an inflation-targeting approach to monetary policy as well as globalization. In particular, inflation targeting by many countries, including Australia, Canada, New Zealand, Sweden, and the United Kingdom, and increased international competition in labor and product markets have contributed to price stability and have put downward pressure on long-term interest rates. This has led to the decoupling of long-term interest rates from short-term interest rates with significant implications for monetary policy. In particular, most central banks use short-term interest rates as their operating instruments, but the effects of monetary policy on economic activity stem from how long-term interest rates respond to short-term interest rates. Hence, a deeper understanding of how inflation targeting and globalization affect the spread between long- and short-term interest rates is needed to evaluate the impact and timing effects of monetary policy.

SPREADS, BID-ASK

The bid-ask spread is the difference between the ask (the lowest price at which someone is willing to sell an asset or security) and the bid (the highest price at which there is someone in the marketplace ready to buy it). The spread is often used as a measure of market uncertainty as well as market liquidity. The average of the bid-ask spread is also
used as a measure of the consensus value of an asset. The term dates back to at least James Dolley, who used it in his March 1938 American Economic Review article to measure discontinuity in stock trading on the New York Stock Exchange, although the concept was probably in use before then.

The intuitive reason for the existence of a bid-ask spread is that there is disagreement among market participants as to the value of a security. However, there are other reasons for a bid-ask spread. For example, because buyers and sellers need not arrive simultaneously, market makers stand ready to buy securities from sellers and sell securities to buyers; the bid-ask compensates these market makers for the cost of holding inventory. Other causes could include the existence of an order-processing cost, or market makers might have to adjust their prices to protect themselves against the risk of trading with better informed agents; this is the adverse selection cost.

One problem with the use of the bid-ask spread is that the market might lack depth—that is, the ability of a trader to trade a large number of shares at the quoted price. Consequently, for average-sized trades, the bid-ask spread might not indicate expected transaction costs. Furthermore, if the potential price impact is asymmetric, the average of the bid-ask spread may not be useful as a measure of the current consensus value of the asset, either.

Alternate measures of liquidity have been suggested. Some of these are: (1) net trading range—that is, the difference between the high and low price less the change in price during a given trading period; (2) the effective bid-ask spread—that is, the distance between the average of the quoted bid-ask spread and the price at which the deal transacts; (3) turnover; and (4) the ratio of absolute returns to trading volume.

Empirically, bid-ask spreads have been linked to various factors such as the volume of trade, the cost of holding inventory, the degree of information asymmetry, and tick size. The first three factors follow immediately from the discussion above. The notion of tick size as a determining factor has acquired more prominence since the introduction of decimalization in secondary equity markets. Decimalization has led to smaller quoted and effective bid-ask spreads for most stocks. However, concomitantly, there have been more small trades and fewer large trades, and the depth of the market has suffered, exacerbating the problems listed above with the use of the bid-ask spread as a measure of liquidity.

SRAFFA, PIERO 1898–1983

Piero Sraffa was born in Turin, Italy, on August 5, 1898. His father, Angelo Sraffa, was a well-known professor of commercial law and then rector of Bocconi University. Sraffa studied law in Turin and graduated with a dissertation titled “Monetary Inflation in Italy during and after the War,” written under the supervision of future Italian president Luigi Einaudi.

INVOLVEMENT WITH KEYNES

During a stay as a research student at the London School of Economics from 1921 to 1922, Sraffa was introduced to the eminent University of Cambridge economist John Maynard Keynes, who was deeply impressed by the young Italian scholar. Keynes invited him to write an article on the Italian banking system for the Manchester Guardian. Upon receipt Keynes decided to publish the piece, titled “The Bank Crisis in Italy,” in the Economic Journal and asked Sraffa to prepare a shorter version for the Guardian. Provoked by the article, Benito Mussolini asked Sraffa’s father to make his son recant the opinion expressed in it, a request that was rejected. In 1923 Sraffa was appointed to a lectureship in political economy and public finance at the University of Perugia. In 1925 he published the influential paper “Sulle relazioni fra costo e quantità prodotta” (in Annali di Economia), which contains an analysis of the foundations of decreasing, constant, and increasing returns in the English economist Alfred Marshall’s theory and a devastating criticism of the partial equilibrium method. Not least because of this essay, Sraffa obtained a full professorship in political economy at the University of Cagliari (Sardinia), a post he held in absentia to the end of
his life. The English economist Francis Y. Edgeworth’s high opinion of the essay led to an invitation to publish a related version in the Economic Journal in 1926 titled “The Laws of Returns under Competitive Conditions.” The paper triggered a debate on monopolistic competition.

In 1927 Keynes arranged for a lectureship for Sraffa at Cambridge. Sraffa began teaching in 1928 on advanced theory of value. He also in the late 1920s began his interpretative and reconstructive work on the classical economists and his criticism of marginalist theory, which finally materialized in his 1960 book, Production of Commodities by Means of Commodities. His breakthrough, in the winter of 1927 to 1928, in regard to his novel interpretation of the classical theory of value and distribution, rendered the task of lecturing increasingly difficult for him. He resigned as lecturer and in 1931 was appointed to the position of librarian of the Marshall Library. In addition he was also placed in charge of the Cambridge program of graduate studies in economics. He gave up lecturing on value theory for good. The only lectures he was to give were devoted to continental banking in 1930 and to industry starting in 1942. In 1939 he joined Trinity College. He was on friendly terms with the Austrian-born British philosopher Ludwig Wittgenstein, who acknowledged to have been deeply influenced by Sraffa.

EDITORSHIP OF RICARDO PROJECT

In 1930 Sraffa was appointed to the editorship of The Works and Correspondence of David Ricardo on behalf of the Royal Economic Society. The project turned out to be much more difficult than Sraffa thought it would be when he assumed the task, not least because a well-known Ricardo scholar, Jacob H. Hollander, effectively boycotted the project for a while. Hollander did not disclose that several “Ricardiana” were in his possession, and when Sraffa proved that they must be, Hollander refused to show them to Sraffa (Gehrke and Kurz 2002). In preparing the edition, the first volumes of which were finally published in 1951, Sraffa was assisted by his friend Maurice H. Dobb. The last volume of the eleven-volume work, containing the general index, was not published until 1973. Sraffa’s introduction to the first volume contains his novel, surplus-based interpretation of the classical approach to the theory of value and distribution. Sraffa held that the classical approach is fundamentally different from the marginalist, demand and supply one and cannot be interpreted as an early version of it. The Ricardo work is widely acknowledged to be a scholarly masterpiece. Interestingly, in 1961, long before the project’s completion, the Swedish Royal Academy honored Sraffa for his work on the project by awarding him a Söderström gold medal in economics, an award that is considered to be a precursor of the award commonly called the Nobel Prize in economics.

In the early 1930s Sraffa was also involved in the so-called Cambridge Circus discussing Keynes’s 1930 work, A Treatise on Money, and his 1936 work, The General Theory of Employment, Interest, and Money. In his paper “Dr. Hayek on Money and Capital,” published in the Economic Journal in 1932, Sraffa managed to effectively ward off an attack on Keynes’s project by the Austrian-born economist Friedrich August von Hayek.

CRITICISM OF MARGINALIST THEORY

From an early time onward Sraffa was particularly critical of two closely related elements of contemporary economic theory. His critical attitude reflects the objectivist or materialist point of view he had developed in discussions with the Italian philosopher and politician Antonio Gramsci and during his intensive reading about recent breakthroughs in the sciences, especially quantum physics (Kurz and Salvadori 2005). The first element concerned the question of whether the parts should be seen as constitutive of the whole, or vice versa. Marginalist economics, starting from methodological individualism, advocated the former view. Sraffa implicitly rejected this position by developing his analysis not from given individual agents but a given “system of production.” To take the whole as constitutive of the parts was also advocated by contemporary scientists, including the English mathematician and philosopher Alfred North Whitehead. Second, Sraffa was critical of the subjectivist element permeating contemporary economic theory and the corresponding concept of “real,” that is, “psychic,” cost (as advocated by Marshall). Sraffa deliberately sought to elaborate an objectivist alternative to marginalist theory revolving around the twin concepts of physical real cost and social surplus within the framework of an analysis that conceives of production as a circular flow.

Sraffa related his reconstructive work explicitly to the works of the English economist William Petty (1623–1687) and the French economist François Quesnay (1694–1774). In his Political Arithmetic (1690), Petty had insisted on expressing himself only “in Terms of Number, Weight or Measure; to use only Arguments of Sense, and to consider only such Causes, as have visible Foundations in Nature” (Petty 1986, p. 244). With the Tableau économique (1758), Quesnay had for the first time put forward a view of the processes of production and distribution of the economic system as a whole. Initially, Sraffa was highly critical of the labor theory of value, as advocated by Ricardo and Karl Marx, because in his view it involved a “corruption” of the earlier concept of physical real cost (Petty’s “food”). It was only after Sraffa had
turned to the case of an economic system with a surplus that is partly distributed to workers in proportion to the time worked that he realized he needed a concept of labor and that in very special conditions relative prices are proportional to labor values. This did not mean, however, that the labor theory of value played any constructive part in his analysis. On the basis of purely objective data (including the share of wages in net income), Sraffa showed that the general rate of profits, the rents of land, and the necessary prices corresponding to the given distribution of the product could be determined. This was an important finding in itself, which at the same time served as the basis for a critique of the alternative marginalist conceptualization. In particular, Sraffa showed that the rate of profits cannot generally be conceived of as determined by the “marginal productivity” of a given “quantity of capital.”

In the second half of the 1950s Sraffa eventually found time to put together, revise, and complete his notes on the classical approach to the theory of value and distribution and publish them as Production of Commodities by Means of Commodities (1960). This book became one of the most often cited books in economics and was translated into several languages. Its findings played an important role in the so-called Cambridge controversies in the theory of capital. The importance of Sraffa’s contribution lies in the fact that he pointed out the dark spots in the marginalist theory of value and distribution and elaborated an alternative to it rooted in the analyses of the classical authors.

STABILITY, POLITICAL

Political stability can be defined as the reproduction of the status quo in political life. The term and its mirror image—political instability—have a decidedly behavioral connotation in most contemporary social science research. As seen by many scholars, political stability is the outcome of interactions by relevant political actors that reproduce the status quo in political life. Conversely, political insta-
Stability, Political

Stability results from interactions that challenge the status quo. To be empirically useful, however, the character of political behavior and whose values or expectations it fulfills (or violates) have to be specified.

The earliest theories of political stability concerned themselves with its societal prerequisites. The prominent sociologist Talcott Parsons (1902–1979) equated political stability with collective legitimacy and the systemic support it afforded. According to Parsons, legitimacy is “the higher normative defense against the breakdown of a system of social order” (Parsons 1966, p. 57). Parsons argued that if citizens did not view the political system as legitimate, they would be particularly prone to support political protest and other forms of antigovernment action. David Easton (b. 1917) further broadened the meaning of legitimacy to include citizen’s perceptions of government institutions as fair, responsive, and valuable.

The difference between citizens who viewed the government as illegitimate but did not join in collective action and those who took part in political protest did not figure prominently in Parsons’s work. For Parsons, the potential for disorder increased with the loss of public confidence in the government. Likewise, Easton argued, only diffuse support through the population gives the system political stability. In their concern with mass political attitudes, these social scientists went beyond a narrow focus on mass political behavior. Their theories, however, were judged as status quo–oriented and suffused with expectations of political behavior and functional roles characteristic of advanced industrialized democracies.

Beginning in the 1970s, social scientists turned their attention to political institutions and the patterns of political behavior they generate. Work on political stability has linked the durability and survival of political regimes with patterns of political behavior. The literature emphasizes institutional consistency and how it affects the behavior of political elites, but mass political attitudes can be used to explain the choices elites make given particular institutional configurations.

Scholars of political institutions have classified political behavior based on three attributes: (1) procedures for selecting the chief executive; (2) constraints on executive decision-making authority; and (3) extent of political participation. This classification results in three basic types of political systems: autocracies, anocracies, and democracies. Autocracies are politics where authority is concentrated and unchecked, whereas democracies are politics where power is diffused. According to scholars of political conflict, anocracies are institutional hybrids combining characteristics of both democracy and autocracy.

Fully autocratic and democratic regimes exhibit the greatest stability. This stability results from the compatibility of their institutions with the behavior of politically relevant actors. Institutionally inconsistent regimes (those exhibiting characteristics of both democracy and autocracy) lack these self-enforcing characteristics. Accordingly, the least stable political systems are autocracies with highly regularized procedures for selecting the chief executive but with high levels of political participation. The most unstable configuration for polities with an elected executive is one where the executive is highly constrained, but the electorate is very small.

The conclusions of institutional scholars can be summarized by a curve with an inverted-U shape: low and high levels of institutional development result in political stability; intermediate levels stimulate political instability. Institutions affect the cost-benefit analysis associated with challenges to authority. The interaction of political actors, in other words, is conducive or detrimental to the distribution of authority in a system of governance.

The work of institutional scholars highlights elite interests and behavior. Mass political behavior, as Parsons and Easton demonstrated, is also necessary to understand patterns of political stability. As the expectation that elites will respect the outcomes of democracy increases, the rewards for compliance with the rules of democracy also increase. This is another way of saying that what is important for a political system is whether institutional continuity is in the interest of the relevant political elites. By raising the cost of noncompliance with the democratic rules of the game, the public has a role to play in the cost-benefit analysis of elites.

One question that was not addressed in studies of political stability until the early twenty-first century is the compatibility of leadership survival with regime stability. Scholars have noted the apparent paradox that while democratic polities are durable forms of government, democratic leaders exhibit a high turnover rate. At the same time, autocratic leaders remain in office for remarkably long periods. The puzzle then is why autocrats tend to remain in power longer than democratic leaders even though autocracies as a group are not more stable than democracies.

According to the secedorate theory of political survival, elites and their supporters in stable democracies have more to lose in the long run by clinging on to power and suppressing their political opponents than by waiting for their turn to be (re)elected to office. Consequently, they choose democracy instrumentally and in the process help increase its legitimacy as a form of government. Autocrats, on the other hand, depend on a narrow coalition to win and remain in power and are widely perceived as illegitimate. As a result, democracies constitute a remarkably stable form of regime even though their leaders last half as long as autocrats.
The selectorate theory explains why protest is prevalent in democracies and rebellion predominates in authoritarian regimes. Because democracies are seen as more legitimate forms of government than autocracies, political protest does not level off as a country democratizes. Yet democracies do not have a demonstrable need to repress peaceful or routine protest. By reducing levels of socioeconomic and political inequality, democracies dampen the temptation to engage in rebellion, which is prevalent in authoritarian settings. Finally, democratization creates political opportunities to engage in more conventional forms of collective action, a point the selectorate theory is well equipped to explain.

STABILITY, PSYCHOLOGICAL
Within any group at every age, human beings vary dramatically among themselves on any given psychological construct, structure, function, or process (let ψ stand for any such entity). It is commonly understood that variation in ψs, whether physical attributes or personality traits, appear in normal distributions in the population. It is important to assess whether differences between individuals in a ψ are fleeting or are stable through time. Thus, psychological science is centrally concerned with assessment of the stability of individual variation. Stability is consistency in the relative standing or rank of individuals in a group on some ψ through time (Figure 1). Stability is particularly pertinent to developmental science and the study of individual variation within a developmental trajectory. An individual with a stable personality trait (say, openness) will display a relatively high level of openness at one point in time vis-à-vis his or her peers and will continue to display a high level at a later point in time, where other individuals display lower levels at both times. Individuals show instability in a given ψ if they do not maintain their relative standing or order in the group through time.

Although developmental science emphasizes overall change and growth, the study of psychological stability is important for several reasons. First, the physiological systems of humans and other living organisms require certain stable conditions—physical, chemical, psychological, and environmental—to survive. These systems also allow for the maintenance of these conditions even in the face of ever-changing circumstances; stability in living organisms is generally in a state of dynamic and adaptive equilibrium. Second, stability provides basic information about the overall developmental course of a given ψ, insofar as individuals do or do not maintain their standing or order on ψ vis-à-vis others in the group through time. Third, it is generally assumed that to be meaningful, a ψ should show substantial consistency across time: a major predictor of ψ at a given age is ψ at an earlier age. Fourth, psychological stability affects the environment: Interactants often adjust to match a consistent ψ in another individual.

Assessment

Stability is consistency in the relative standing or rank of individuals in a group with respect to the level of some characteristic (ψ) through time.

Figure 1
Development is governed by genetic and biological factors in combination with environmental influences and experiences. Stability of any $\psi$ could be attributable to genetic or biological factors in the individual, or stability might emerge through the individual's transactions with a consistent environment. Personality traits tend to be stable across time and can serve as examples of a developmentally stable $\psi$. Current models describe personality as consisting of five factors, openness, neuroticism, extraversion, agreeableness, and conscientiousness. According to this five-factor trait theory, traits are endogenous dispositions that follow intrinsic paths of development essentially independent of environmental influences.

In the context of developmental science, consistency may have many applications and its evaluation may take many different forms. Longitudinal developmental design is requisite to addressing questions about consistency. Furthermore, it is desirable to distinguish between consistency among individuals, or individual order consistency (stability/instability), and consistency in a group, or group mean level consistency (continuity/discontinuity). Order consistency and mean consistency are independent or orthogonal constructs. Conceptually and empirically, the two can exist simultaneously, and both have been reported in the same longitudinal study of different $\psi$s. Normally, stability is assessed using (Pearson or Spearman) statistical correlation.

It is further desirable to distinguish among types of stability. There are three prominent models of possible temporal association. One model describes homotypic (sometimes called complete) stability: the maintenance of order among individuals in the same $\psi$ through time. This applies to some personality traits; individuals displaying high levels of openness in relation to others at Time 1 will display relatively high levels of openness relative to others at Time 2. A second model describes heterotypic stability, which is the maintenance of order among individuals on different manifest $\psi$s through time where the different $\psi$s are theoretically related and presumably share the same latent process (e.g., positive affectivity in personality, say, underlying the traits of openness and sociability). Thus, $\psi_a$ (e.g., openness) at Time 1 relates to $\psi_b$ (e.g., sociability) at Time 2. Models of heterotypic stability typically postulate that some shared $\psi_i$ in the individual underlies stability between $\psi_a$ and $\psi_b$. A third model of mediated stability describes the stability in $\psi$, or the stability between $\psi_a$ and $\psi_b$, as explained by a mediating variable $\psi_s$ that is not in the individual but remote from $\psi$. For example, $\psi_s$ (e.g., openness) at Time 1 relates to $\psi_a$ (e.g., openness) or $\psi_b$ (e.g., sociability) at Time 2 because some $\psi_s$ that is shared with each is itself stable (e.g., a positive environment). This model predicts that, once the contribution of $\psi_s$ is removed, stability in individuals will attenuate.

Stability itself varies, and variation in stability depends on the $\psi$ (some $\psi$s may be more stable than others); on the age of the individual when the stability of $\psi$ is assessed (a $\psi$ may not be stable in infancy, but stabilize in adulthood—people are thought to become increasingly consistent in relation to one another as they age); on the assessment of $\psi$ (the less information about $\psi$, the lower its stability estimate); on the temporal interval between assessments of $\psi$ (the shorter the interassessment interval, the greater the stability estimate of $\psi$); and on whether assessments are made across consistent or inconsistent contexts (the former improves stability, and the latter attenuates stability).

Why might stability fail? If a $\psi$ is not stable, there are two possible explanations: Either $\psi$ is not stable, or $\psi$ has not been assessed adequately. Barring measurement imprecision, we attribute instability to genetic and biological as well as environmental and experiential forces. The timing of biological phenomena is partially driven by genetic factors and tends to happen within a specific period of the life course for most people in any particular population. Change also arises because people engage in normative life tasks and roles, such as leaving home, establishing a family, and starting a career. The life span perspective in psychology specifies that human beings are open systems, and the plastic nature of psychological functioning ensures that people exhibit both stability and instability in many $\psi$s throughout the life course.

STABILITY IN ECONOMICS

The concept of stability in economics is closely related to the concept of equilibrium and is one of the three properties of equilibrium that is routinely studied by economic theorists (the others being uniqueness and existence). Economists typically use the term stability to denote what mathematicians call asymptotic stability. Hence an economic system (such as a firm, a market, or even an entire economy) is stable if, following some displacement of the system from equilibrium, it adjusts so as to regain its original equilibrium position. The concept of stability can be demonstrated by the behavior of a conventional (Marshallian) commodity market, in which supply and demand interact to determine both price and quantity traded. If the price level in such a market is dislodged from its equilibrium (market-clearing) value, the resultant excess demand (or supply) gives rise to subsequent changes in the price level that will restore conditions of equilibrium.

A stable equilibrium may be either a point (such as a particular value of the unemployment rate) or a path (such as a limit cycle describing regular fluctuations in national income). Furthermore, an equilibrium may be either stable or unstable depending on initial disequilibrium conditions. Indeed, if stability is observed only when an economic system is not displaced “too far” from equilibrium, then the system is described as being only locally stable. In economic systems with multiple equilibria, for example, individual equilibrium positions can only be locally stable. If stability is observed regardless of the initial distance from equilibrium, however, the system is said to be globally stable.

Stability is not always regarded as an important or good thing in economic theory. For example, instability is sometimes essential to the motion of the economic system that is being theorized, as in the English economist John Hicks’s famous theory of the business cycle. Elsewhere, saddle-point instability is important for solving the problem of the choice of disequilibrium adjustment path in certain models involving rational expectations. Some economists, meanwhile, argue that stability is an unnecessary feature of equilibrium analysis. They suggest that unstable equilibrium models generate the useful empirical claim that the current outcomes of an economic system will not persist in the future. Finally, as will become clear in the discussions of path dependence and resilience below, other economists regard stability as an analytical straitjacket that discourages routine exploration of the possibility that economic systems display richer dynamics.

SPEEDS OF ADJUSTMENT AND THE USEFULNESS OF EQUILIBRIUM

This having been said, the prevalence of equilibrium analysis in economic theory means that most economists seek to prove (or, very often, simply assume) the stability of equilibrium most of the time, and with good reason. First, it is essential that an economic system be able to “get into” equilibrium if the latter is to be useful as a description of the actual configuration of the system at any point in time. Second, the method of comparative statics/dynamics, on which so many of the results and policy conclusions of economic theory are based, is predicated on the stability of equilibrium.

The usefulness of equilibrium for describing the outcomes that one might expect to observe in an economic system depends, in fact, not just on stability but also on the speed of disequilibrium adjustment. Unless equilibrium is reached sufficiently rapidly, it may not be interesting as a description of system outcomes over a particular time horizon. Indeed, if adjustment is so slow that the data defining an equilibrium configuration autonomously change before the equilibrium itself is attained, then even analytically stable equilibrium may never be reached in practice, rendering it meaningless as a description of system outcomes over any time horizon. The speed of disequilibrium adjustment is an issue to which economists who rely on equilibrium analysis seldom pay sufficient attention.

STRUCTURAL STABILITY AND PATH DEPENDENCE

The potential for the data defining an equilibrium position to change in the course of disequilibrium adjustment draws attention to two further issues connected with stability in economics. First, a stable economic system must also be structurally stable if it is to attain equilibrium. This means that, over the course of disequilibrium adjustment, the data defining the system must be subject to only small variations that do not fundamentally alter the character of the system’s motion (by converting a stable system into an unstable one, for example). Structural stability is rarely addressed by economists, who instead usually assume that data remain literally constant in the course of disequilibrium adjustment.

Second, the adjustment dynamics of a system may be affected by path dependence. A conventional, stable equilibrium can be described as determinate in the sense that it is both defined and reached independently of the path taken toward it. But if disequilibrium adjustment changes the data defining an equilibrium and hence changes the equilibrium configuration itself, then the equilibrium is indeterminate or path-dependent. For example, if disequilibrium trading results in a particular consumption experience that would not have existed in the absence of disequilibrium conditions, and if this experience alters household preferences (a shortage may enhance the perceived desirability of a commodity, for instance), then the
Stages of Development

exact equilibrium configuration of a Marshallian commodity market will be affected by the history of its disequilibrium adjustment, and will thus be path-dependent. As this example illustrates, an indeterminate or path-dependent economic system may eventually reach an (historically contingent) equilibrium position, in which case it is said to be definite-indeterminate. Such a system may be said to display “weak” stability in the sense that, although its outcomes are path-dependent, a position of equilibrium is eventually attained. This contrasts with the “strong” stability characteristic of determinate systems, which converge onto fixed points or paths defined independently of the system’s prior adjustments.

However, an indefinite-indeterminate system will never “settle down” into a state of equilibrium (thus lacking even “weak” stability), but will instead remain in continual, path-dependent motion. A path-dependent equilibrium position may exist at any point in time in an indefinite-indeterminate system, but such positions are continually being redefined and are never reached, so that they never serve as interesting descriptions of the system’s outcomes. Note that indeterminacy or path dependence is not the same as instability. The latter involves movement away from a fixed point or path. Path dependence, on the other hand, involves redefinition of the equilibrium point/path in the course of disequilibrium adjustment. In path-dependent systems, an equilibrium may exist and attract the system toward itself. But the equilibrium will be redefined by the resulting motion of the system and, as a consequence of the system thus “chasing a moving target,” may never be reached. Unfortunately, economists typically assume away path dependence when dealing with the stability properties of equilibrium models, with the result that any sense of the historical contingency of economic outcomes is lost. Work on hysteresis and lock-in in economics—concepts that show how events in the past can permanently affect current and future economic behavior and outcomes—can be understood as attempting to rectify this state of affairs.

STABILITY OR RESILIENCE

Finally, the behavior of indefinite-indeterminate systems prompts the question as to whether economists should pay more attention in future research to the resilience rather than the stability of economic systems. Stability analysis focuses on a precise outcome or configuration of a system, and the capacity of the system to return to this constant point or path over time. The concept of resilience, meanwhile, focuses on the durability of the system itself and hence its capacity for longevity. The key question addressed in the study of resilience is coarser and more qualitative than that addressed by stability analysis: Can the system as a whole reproduce itself in a sufficiently orderly fashion, and thus persist over time? Hence an indefinite-indeterminate system—which displays neither “weak” nor “strong” stability properties—may nevertheless be very resilient. Whether stability or resilience is the more important property of an economic system is likely context-dependent. For example, if a concert hall is to be economically viable, it may be very important for that hall to ensure that the volume of its public address system remains essentially constant and that any variations in volume are rapidly eliminated by movement back toward equilibrium. However, it may be far more important for an exchange-rate regime to help reproduce orderly conditions of international trade and finance over time, than for it to ensure the movement of a particular exchange rate toward some predefined value identified by economists as an equilibrium.

STAGES OF DEVELOPMENT

Stage theories of development are sometimes called discontinuity theories. The premise is that development occurs in discontinuous stages: During a particular stage, a child will go through no significant changes in his or her abilities or capacities, and behavior will remain fairly stable within that stage. Later development will take the
individual to a more mature stage, at which point there is again a kind of stability. This view is in direct contrast to continuity theories, which describe development as a continuous process without stages or phases.

**FREUD**

Freud presented one of the first stage theories of development, with different components of the personality developing in each. The theory focused on psychosexual development and described five stages: the oral stage, birth to eight months; the anal stage, eight to eighteen months; the phallic stage, eighteen months to six years; the latency stage, six to eleven years; and the genital stage, which is, in a sense, maturity. The id, a reflection of instinct and libido, is all important in the oral stage. The ego develops in the second stage. Both the Electra and Oedipal complexes occur in the third stage, as does the superego and thus the individual’s conscience. The latency stage reflects a kind of loss of interest in sexual gratification; more important in this stage is the child’s identification between him- or herself and the parent of the same sex. The genital stage allows the individual to develop adult sexual concerns. An individual may develop a fixation that prevents moving from one stage to another; for example, an individual with an oral fixation continues to seek pleasure through the lips and mouth, even as an adult. Various forms of regression may also occur when an individual returns to an earlier, less mature mode of psychic functioning.

**ERIKSON**

Although Freud’s theory has been widely criticized and has remained the subject of much debate, its impact on subsequent developmental psychologists and clinicians is beyond doubt. Erik Erikson, the German developmental psychologist, studied with but then broke away from Freud to develop his own stage theory. Whereas Freud emphasized childhood and preadolescent development, Erikson’s theory covers the life span, with eight stages; whereas Freud’s psychosexual theory emphasized the libido and its expression in the different stages of development, Erikson’s psychosocial theory emphasized the social environment. Each stage is characterized by a conflict or crisis, and each crisis has its origin in the interaction between the individual and the social environment. For example, in the first stage the crisis involves trust versus mistrust; Erikson felt that the individual must learn to trust others and him- or herself to develop a healthy personality. The eighth and final stage involves the crisis of integrity versus despair.

**PIAGET**

The most commonly cited cognitive stage theory was developed by the Swiss psychologist Jean Piaget. Piaget described four stages of development, each of which involves an idiosyncratic kind of thinking. Movement through these stages is typically completed sometime during adolescence. The first stage, the sensorimotor, lasts approximately two years, during which time the individual’s cognition is processing only sensory and motoric information; he or she does not think beyond the here and now and cannot contemplate anything abstract or hypothetical. The individual adapts to the environment through the processes of assimilation (the individual manipulates information such that he or she can think about it and perhaps adapt to it) and accommodation (the individual’s cognitive structures change in response to the experiences). Piaget used this adaptive process to explain all cognitive growth, deeming other kinds of what he termed learning superficial, almost a kind of memorization. Adaptation, on the other hand, requires a change in the individual’s cognitive structures, and this depends on the adaptive process.

In the second stage, the preoperational, approximately ages two to seven, the individual moves beyond the here and now but still is not capable of cognitively operating on information. The third stage is the concrete operational, approximately ages seven to eleven, in which children begin to apply logical thinking to concrete events and objects. The fourth and final stage is the formal operational, from about age eleven on, at which point individuals are, for Piaget, “little scientists”: they can take a number of variables into account when making logical decisions, and sometimes they are even scientific in the sense of reasoning about certain factors in isolation. The formal operator is, for Piaget, cognitively mature and able to apply logic to hypothetical (not just concrete) things, to reason sociocentrically (not egocentrically), and to think about various propositions. The formal operator also can be very effective with deductive logic. Piaget described how thinking in a deductive fashion (rather than relying on the less mature forms of transductive or inductive thought) depends on and supports hypothetical thinking. He referred to them as one process, the hypothetico-deductive process.

Several neo-Piagetians have proposed fifth and sixth stages of development in an effort to describe cognitive changes occurring in adulthood. Neo-Piagetians have also pointed to other skills, including relativistic thinking, a problem-finding capacity, and dialectical thinking. The first of these implies that the individual does not think in black and white or absolutes. The second implies that the individual not only can solve problems logically but can also identify them and define them in a manner that allows creative solution. The third, an ability to accept and reason dialectically, allows the individual to accept a thesis as well as its antithesis and integrate them, the result being a useful synthesis.
Piaget recognized that stages do not develop without particular experiences. They are dependent on genetic potentials, and indeed Piaget referred to his theory as a genetic epistemology. Epistemology is the study of knowledge; but by genetics Piaget was referring not to the chemical makeup of life—he was writing before technologies existed for the identification of genes themselves—but rather to the biological basis for development, and to potential. But adaptation is necessary for development. This is very important because it implies that individuals will not necessarily move through these stages; they move through them only when they are biologically ready and have had appropriate experiences. These experiences must challenge an individual and elicit adaptations.

In contrast to stage theories, continuity theories hold that development occurs unrestricted by stages. Learning theories reflect continuity theories, for they typically suggest that individuals have a stable potential to learn: the more experience one has, the more mature and capable the individual will become. In stage theories, biological or perhaps psychological factors interact with experience such that individuals can benefit from experience only if they are ready to do so.

STAGES OF ECONOMIC GROWTH
The attempt to search for a common set of general stages in the historical development of nations and their economies goes back to Adam Smith, who defined four stages of societal organization: the original stage of hunters, a second stage of “shepherds” or nomadic agriculture, a third stage of feudal “farming agriculture,” and a fourth and final stage of commercial society.

The most commonly accepted set of stages are those postulated by Walt Whitman Rostow, who in The Stages of Economic Growth (1960) proposed the stages as a general model of economic change. Rostow’s model assumes that it is possible that all societies during their development appear in one of five stages of economic development: the traditional society, the preconditions for takeoff, the takeoff, the drive to maturity, and the age of high mass-consumption. While this discussion will only consider the economic dimension of the stages, Rostow also outlined non-economic social, political, cultural, and psychological factors. However, in the classification of particular countries’ development, he emphasized the economic factors.

DEFINITIONS OF ROSTOW’S STAGES
The first stage, the traditional economy, is characterized only by basic industries: agriculture and mining. The economy is unproductive, society is based on pre-Newtonian science and technology, and the labor force is unskilled. The attainable level of output per capita is limited. The second stage of growth, the preconditions for takeoff, finds economies in the process of transition, as the traditional society starts to exploit the results of modern science. While the society can still mainly be characterized by traditional low-productivity, there are already productivity improvements in agriculture and extractive industries that create savings that can be invested in infrastructure. The supportive role of government is very important at this stage. During the third stage, the “takeoff” stage, the rates of productive investment and saving rise further and new industries grow rapidly, using new techniques of production. The process of industrialization is driven by the leading sectors of industry, such as railroads and steel, and stimulates the growth of other industries. The fast growth of productivity in agriculture is an important condition for successful takeoff. The economy and its social and political structure are transformed so that the growth can be sustained. After the takeoff stage, as new and more advanced industries develop and modern technology is applied to all industries, the economy enters the fourth stage, the drive to maturity. The fifth and final stage of growth is that of high mass-consumption, when all the leading sectors move toward durable consumer goods and services and the service sector experiences rapid growth. The most developed countries, like the United States, are now considered to be in this stage.
Rostow tried to establish a general “theory” of development, based on a dynamic neoclassical theory of production. He did not, however, provide a formal “model” of the stages, but only a set of narrative descriptions, so that the result was “less a theory than a language” (Supple 1984, p. 114). Rostow “linked theoretical constructs (like production functions, capital-output ratios, propensities to invest and to consume) to the dynamics and narrative of historical change, and acknowledged the vital significance of sociopolitical attitudes, groupings, and discontinuities” (Supple 1984, p. 108).

Rostow presented and described empirical and historical evidence for the most advanced countries, especially Great Britain, to support the view that the modern development of these countries had gone through the same stages. This work gave impetus to more careful, longer-term empirical research that ultimately failed to support Rostow’s conclusions—for example, it failed to “identify a takeoff in the economic history of countries such as France” (Crafts 2001, p. 308).

Aside from these theoretical criticisms, there were more general criticisms that may also be applied to current-day economic theories of growth and development. According to Edward S. Mason (1982), principal flaws include an overemphasis on discontinuity in historical processes, the teleological character of the conception of development, and problematic generalizations of political processes. R. de Oliveira Campos (1982) criticizes the presumption of the universality of economic motivations and of the inevitability of growth, without any space for economic decline and reversals. For W. Arthur Lewis (1982), what is missing is the crucial role of institutions; for Douglass C. North and Peter Temin (1982), it is the concept of transaction costs. Despite all these criticisms, Rostow’s stages of growth undoubtedly contributed to or at least were consonant with the early thinking about economic development as a process, and concepts such as the takeoff or leading sectors have been accepted by the profession. As Supple remarks, “even Rostow’s critics adopt his terminology” (1984, p. 108).

STAGES OF ENDOGENOUS GROWTH
Rostow’s stages of growth have stimulated recent attempts in the field of growth theory to construct more general formal models able to capture the behavior of developed and less-developed economies. One of the first such models was developed by Costas Azariadis and Allan Drazen (1990), who used the endogenous growth model with human capital as an engine of growth, an approach first suggested by Robert Lucas (1988), but amended it by adding “threshold” externalities in the human capital sector. Such a model exhibited two steady states: the regime of the zero-growth, underdevelopment trap, and the regime of sustained growth. When the underdeveloped economy manages to accumulate a critical amount of human capital, it reaches an area of increasing returns stimulating even more investment in human capital, and the economy takes off into sustained growth. By explicitly modeling knowledge-diffusion, Fabrizio Zilibotti (2005) in the AK model and Michal Kejak (2003) in Lucas’s model construct a model able to exhibit different stages of growth. (Mentioned here are only a handful of the numerous growth models with multiple steady states, as many of the others are not linked to Rostow’s stages of growth.)

UNIFIED THEORY OF GROWTH AND DEVELOPMENT
Growth-theory literature on models with multiple steady states laid the grounds for the establishment of a “unified” theory of growth and development that aims to capture in a single unified framework the era of Malthusian stagnation, the modern stage of sustained growth, and the transition between these two regimes—industrial revolution. Lucas (2002) offers such a model of the industrial revolution, in which human capital serves as an engine of sustained growth. An important part of this model’s mechanics is a Beckerian trade-off between the quantity and quality of the children responsible for demographic transition. A similar model with non-homothetic preferences is presented by Oded Galor and David N. Weil (2000). An alternative model of the industrial revolution in which new ideas are seen as an engine of growth can be found in the work of Charles I. Jones (2001). An even simpler model with exogenous growth in technology improvements is presented in works by Gary D. Hansen and Edward C. Prescott (2002) and Stephen L. Parente and Prescott (2004).

POLITICAL AND POLICY CONSEQUENCES
Rostow wrote The Stages of Economic Growth as an “Anticommunist Manifesto” (to quote the book’s subtitle)—that is, as a liberal’s reply to Marxist analysis (Soviet 2005). He considered those societies in the transition from a traditional to a modern state especially vulnerable to communist development, which he calls “a disease of transition.” Rostow’s aim was to offer an attractive and achievable means of development for less-developed countries, as an alternative to dependency theory and development toward communism.

The ideological and political consequences of Rostow’s stages of growth can best be guessed from his own political and policy-making activities. After publishing The Stages, he became an adviser to the American presidents John F. Kennedy and Lyndon B. Johnson and later
the chairman of the policy Planning Council at the State Department. Rostow’s theory “became a cornerstone in American international policy towards the Third World” (Solivetti 2005, p. 722).

The only policy recommendation derived from Rostow’s stages of growth has been the principle that take-off into “self-sustained growth” requires a large increase in investment. Unfortunately, aside from the Marshall Plan for the reconstruction of Western Europe after World War II, this policy has not been successful in dealing with underdeveloped economies. As William Easterly (2001) points out—according to Solow’s original insight—“capital fundamentalism” has failed to advance growth in poor countries. The foreign aid based on “financing the gap” has not delivered any results, and it has created wrong economic incentives.

Recent achievements in the unified theory of growth and development, besides contributing to a better explanation of past economic development, have also created strong claims for the effects of government policies on economic development. Despite the fact that empirical work on policies and growth, embodied mainly in cross-country growth regressions, has tended to confirm these claims, real-world experience has not satisfied expectations. In recent debates over this failure several shortcomings have been identified. In empirical studies on growth, it has been claimed, the conventional approach suffers from several statistical problems (Durlauf 2002), results are often driven by extreme observations (Easterly 2005), and there are nonlinear interactions between policy and growth once institutions are controlled for (Aghion and Howitt 2006). Furthermore, most existing theoretical development models ignore the informal sector (Easterly 2005) and/or do not properly model technological change (Aghion and Howitt 2006).

BIBLIOGRAPHY

STAGFLATION
Two main yardsticks of a modern economy’s performance are the rate of growth in the production of goods and services and the inflation rate. When the production of goods and services is growing slowly or is falling (generally accompanied by a rising unemployment rate), stagnation occurs. When the prices of goods and services are rising, inflation occurs. Stagflation, a term attributed to the British politician Iain Macleod, refers to a situation in which an economy experiences stagnation and inflation simultaneously.

As recently as the 1960s, the conventional wisdom in macroeconomics was that inflation and stagnation could not appear at the same time. Economists generally believed that there was a stable, inverse relationship between the rate of inflation (the percentage change in the average level of prices) and the unemployment rate (the percentage of the labor force that is unemployed) as illustrated by the Phillips curve, made famous by the New Zealand economist A. W. H. Phillips (1914–1975). The Phillips curve presented policymakers with a trade-off: They could lower unemployment by stimulating demand but at the cost of higher inflation; or they could lower inflation but at the cost of higher unemployment. Policy discussions in the 1960s centered on which point on the Phillips curve was most desirable.

Consistent with the Phillips curve trade-off, the 1960s saw inflation in the United States increase and unemployment decline, with the unemployment rate falling to 3.5 percent by 1969 while inflation rose to 6.2 percent. In 1970, however, the unemployment rate increased substantially to 4.9 percent with little decrease in inflation. This was the start of a dismal decade for the large industrialized economies. As a whole, the Group of Seven (the seven largest capitalist economies) saw inflation double and real growth halve compared to the 1960s. This experience of relatively high inflation, slow growth, and high unemployment kindled interest in the causes of stagflation.

EXPLANATIONS FOR STAGFLATION
Economists developed two explanations for stagflation in industrialized economies. The first sees stagflation as a phase in an economic cycle that begins with excessive growth in spending, typically fueled by higher-than-normal growth in the money supply. Initially the growth in spending causes prices to rise and, in response, firms to expand production and employment so that the economy experiences higher inflation and lower unemployment. As argued by the American economists Milton Friedman (1912–2006) and Edmund S. Phelps (b. 1933), the decline in unemployment results from the higher inflation being unexpected so that real wages (i.e., wages adjusted for inflation) fall. Lower real wages lead workers to demand higher real wages, commensurate with higher expected inflation, in the second phase of the economic cycle, causing the unemployment rate to rise back toward what Friedman called the natural rate of unemployment, the level of unemployment that occurs when actual and expected inflation are equal.

The first explanation fits the U.S. stagflation of 1970. According to this view, the rising inflation of the 1960s caused expected inflation to increase, shifting the Phillips curve up in 1970, with the result that inflation remained high while the unemployment rate rose. The U.S. wage-price controls of the early 1970s were an attempt to lower expected inflation and shift the Phillips curve downward, in the hope of reducing inflation without having to increase unemployment.

The second explanation for stagflation focuses on autonomous events that make production more expensive and cause firms to raise their prices. This view is more relevant to the general stagflation of the later 1970s, the source of which is thought to have been the large increases in oil prices in 1973 and 1979. Given that energy is an important component of most goods, a large increase in energy prices increases the costs of production for most firms. Firms are willing to supply the same level of output only if their prices rise. The oil price increase is referred to as an aggregate supply shock. It triggers firms to raise prices and lower output. An adverse supply shock such as a large increase in energy prices shifts the Phillips curve upward and again results in both inflation and rising unemployment.

Not all economists believe that the stagflation of the later 1970s can be blamed on oil prices. Robert B. Barsky and Lutz Kilian (2002), for example, believe the first explanation holds for this episode too. They argue that the stagflation occurred largely because policymakers believed the natural rate of unemployment was lower than it actually was, leading them to overstimulate spending in a misguided attempt to push down the unemployment rate. The explanations are not mutually exclusive so that both may have contributed to the stagflation of the 1970s. An adverse supply shock should not cause sustained higher inflation unless accompanied by higher rates of growth in the money supply.
Developing countries, particularly in Latin America, have often suffered bouts of stagflation. An alternative explanation for stagflation in such economies focuses on the macroeconomic effects of exchange rate devaluations, as analyzed for example by Paul Krugman and Lance Taylor (1978). Most developing economies have fixed nominal exchange rates. If there is a balance of payments deficit, international agencies often prescribe a devaluation of the currency in order to reduce trade deficits. Such devaluations, however, may lead to short-run decreases in output along with higher inflation. Given rigidity in nominal wage rates and prices marked up from costs, the devaluation can result in reduced domestic aggregate demand because of the redistribution of income away from labor, which is assumed to have a higher marginal propensity to spend. Domestic demand can also fall from the decline in real money holdings as prices rise in response to higher import costs and from the increase in ad valorem taxes on imports. Thus devaluations can lead to periods of stagflation.

POLICY RESPONSES
The appropriate policy response to stagflation depends on its cause. If the stagflation is the result of policy-initiated excessive stimulation of spending so that the unemployment rate falls below the natural rate initially and then rises along with inflationary expectations, policymakers need to admit their error and to convince people that they should not build higher inflation rates into contracts. The problem, of course, is that people will be skeptical, so that the policymakers will need to establish credibility that they are truly adverse to inflation.

The suitable response to stagflation caused by aggregate supply shocks is less clear. One response is to do nothing and let the economy adjust as best it can to the shock. If energy prices will be permanently higher, the economy needs to make the changes to the new environment. The likely outcome is a short burst of inflation and a rise in unemployment followed by a gradual return to lower unemployment and stable prices. If energy price increases are temporary, policymakers may choose either to reduce the unemployment effects (by stimulating spending and increasing inflation) or to reduce the inflation effects (by restricting spending and increasing unemployment). The latter choice was the one taken by the administration of Gerald R. Ford after the 1973 oil price shock when it tightened monetary and fiscal policy in 1974 and exhorted households to cut spending as part of President Ford’s famous “Whip Inflation Now” (WIN) campaign. The result was a large increase in unemployment with a peak unemployment rate of 8.5 percent in 1975.

Beginning in the early 1990s, inflation targeting by central banks has been advocated as a solution to the first cause of stagflation. If adopted, however, this policy will make the unemployment effects of supply shocks more severe because the response of policymakers will be to reduce spending growth in order to slow the inflation rate. A flexible inflation target that allows for short-run bursts of inflation from supply shocks is one possible remedy.

STAGNATION
Stagnation is a condition of an economy in which its rate of total output, or per capita output growth, is at—or close to—zero for a relatively long period of time. (Sometimes the term is applied to particular sectors, but in this entry it refers to the entire economy.) Stagnation is sometimes characterized by high rates of unemployment. It can be distinguished from other terms such as recession or depression, which usually refer to periods of low or even negative rates of growth but which are relatively short-lived phases of the business cycle. If stagnation is accompanied by high inflation, the phenomenon is called stagflation (although this may sometimes merely be a phase of the business cycle). The term stagnation is used both for economically advanced countries that have experienced growth in the past and have a high level of per capita income and for less-developed countries that have failed to grow.

The analysis of stagnation in this economic sense, as well as in broader terms, has a long history. The fourteenth-century Arab scholar Ibn Khaldun discussed the tendency of empires and societies to stagnate due to the erosion of solidarity and the spread of habits of luxury among rulers. In the twentieth century, this broad view about the rise and inevitable decline of civilizations was pursued by German philosopher Oswald Spengler (1880–1936), who analyzed...
stagnation in terms of factors like the domination of politics by the power of money and the concentration of populations in “barrack-cities” that turn people into mobs susceptible to demagoguery. This view was also explored by historian Arnold Toynbee (1889–1975), who examined how mature civilizations, due to the “intractability of institutions,” for instance, are unable to respond appropriately to challenges and therefore suffer stagnation. Heavy tax burdens and the corruption and excessive luxury of the ruling classes have often been highlighted in historical studies of stagnation. Stagnation in precapitalist countries was attributed by Adam Smith (1723–1790) to inadequate laws and institutions and to the neglect of foreign trade. Broad analyses of the problems of less-developed countries explain stagnation in terms of political and social factors. For instance, those enjoying political power and doing well outside of the economy are argued to be unwilling to make changes to institutions and policies that are likely to worsen their own positions.

In more narrowly economic terms, stagnation in advanced economies has been explained both in terms of supply-side and demand-side factors. Factors on the supply side were stressed in the classical theory of the stationary state. In David Ricardo’s (1772–1823) analysis of the growth process, as more capital is accumulated and more workers are hired, the demand for food to be consumed by workers increases, which drives agricultural production onto increasingly less fertile land, increasing the competition for land, driving up land rent, and reducing the profits out of which capital is accumulated, which eventually brings capital accumulation to a halt. While Ricardo may have underestimated the extent to which diminishing returns to agriculture can be offset by technological improvements, the main reason for his stationary state—that is, diminishing returns—continues to be stressed. In Robert M. Solow’s 1956 model, for instance, as capital is accumulated, diminishing returns to capital set in to make saving and investment sufficient only to keep the capital-labor ratio constant, which implies a constant level of per capita income, unless exogenous technological change makes per capita output grow. The assumption of diminishing productivity of capital and other produced inputs has more recently fallen into disfavor, with empirical evidence suggesting that technological change and external economies can defeat the effects of diminishing returns, as usually assumed in new growth theory models. But structural changes increasing the weight of technologically lagging service sectors and environmental constraints remain possible causes of stagnation.

For the demand side, it was argued by John Maynard Keynes (1883–1946) that, in advanced economies, saving as a ratio of output tends to rise with increasing output and income as consumer wants are increasingly satiated, while investment incentives progressively decline with capital accumulation. With lower rates of investment and consumption, aggregate demand declines, and the rate of growth of output slows. These insights were used by Alvin Hansen (1887–1975) to develop a theory of U.S. stagnation in the 1930s due to inadequate aggregate demand. Subsequent events have shown that government aggregate demand policy can rescue economies from deficient aggregate demand and that there seems to be no inherent tendency for satiation in consumption. Nevertheless, governments may be unable or unwilling for political reasons to solve the problem of demand deficiency, and structural changes rather than any inherent tendency for consumption demand to become satiated may continue to make demand factors relevant. Josef Steindl (1912–1993) argued that the rise of monopoly power made possible by increasing industrial concentration tends to increase profit markups, which tends to increase saving in the economy, leading to a reduction in aggregate demand, a decline in capacity utilization, and a consequent decline in investment. Paolo Sylos-Labini (1920–2005) stressed problems created by the growth of oligopoly on the nature and consequences of technological change, which tended to increase profit margins of large firms and reduce aggregate demand.

Explanations of stagnation in less-developed countries sometimes focus on the demand side, for instance, stressing the absence of investment incentives due to the small size of markets and the high levels of uncertainty caused by external and internal shocks, and sometimes the supply side, emphasizing low saving and productivity. Many of the explanations invoke the concept of the vicious circle, according to which low per capita income, through a variety of channels, implies its persistence (see Nurkse 1953; Leibenstein 1957). The plethora of such mechanisms under discussion, in addition to low saving and investment incentives, include: poor nutrition and health and low productivity; low income, absence of collateral, and the inability to borrow and finance economic projects; and poverty, child labor, and low levels of education and human capital accumulation. More recently, vicious circles have been related to poor institutions, governance, corruption, and violence. Low levels of income may make corruption and violence more attractive, leading to poor economic performance. Some approaches examine how increases in per capita income may set off forces that lead to subsequent declines. Examples of such mechanisms include increases in population caused by better living conditions, which reduce per capita income; increases in consumption from very low levels when income increases; and the inability to adopt increasing-returns technologies that require a minimum size of the market (see Azariadis and Stachurski 2005). These mechanisms produce low-level poverty traps: if per capita income is initially below a critical minimum level, the
economy will converge to a poverty trap, whereas if the economy happens to attain a level beyond that critical minimum, it sets off into self-sustained growth.

The newer approaches suggest that stagnation is not inevitable for advanced economies, and poor countries can escape from their low-level traps under certain circumstances. However, these approaches also suggest that broader political, social, and institutional factors emphasized in earlier approaches have continued relevance insofar as they interact with more narrowly defined economic factors in explaining stagnation.

STAKEHOLDERS
Stakeholders are constituencies who are affected, voluntarily or involuntarily, by the actions taken by an organization, such as a corporation. Commonly cited examples of corporate stakeholders are employees, financial intermediaries, shareholders, customers, and suppliers, all of whom are affected by, respectively, a firm’s compensation and hiring decisions, investment choices, dividend and share repurchase policies, product-related issues, and material purchases. The term, however, is often more broadly applied to include local, state, and federal governments because firms pay taxes and use public resources; it can also be extended to include the local community because firms interact with the natural environment and engage in philanthropic activities; and furthermore, because many firms operate on an international scale, it may even include the global community.

Stakeholders may raise issues of concern with corporations and suggest actions that corporations should take. For example, if shareholders are concerned that a corporation is holding too much money, they may argue for increased dividends. Constituents from a local community concerned with air quality may urge a corporation to invest in cleaner technologies. Even though they are not legally required to do so, corporations may consider and implement stakeholders’ ideas because they provide a host of resources to corporations. Lenders and shareholders make financial resources available, employees and suppliers provide physical inputs, governments supply regulatory oversight, and citizens contribute to the social environment in which operations occur. In short, a corporation cannot exist without the support of a diverse set of stakeholders.

A corporation must consider the principles of stakeholder theory or stakeholder management when it decides which stakeholders to acknowledge and how to best respond to their often incompatible requests. The notion of stakeholders originated in the mid-1960s, but it was in the 1980s that, as evidenced by Edward Freeman’s 1984 book Strategic Management, the idea of stakeholder management began to gain ground in the field of economics. Stakeholder theory represents a significant departure from the older principal-agent view of the firm, which effectively recognizes shareholders as the only legitimate constituency by nature of their ownership position. Stakeholder theory, in contrast, understands the corporation in law and in practice as more than an extension of shareholders with narrow, well-defined goals. Rather, the corporation is viewed as its own entity with its own rights and obligations. As the trustees of the firm, usually its board of directors, are responsible for the firm, they can and should serve other constituencies for the benefit of the corporation. Furthermore, in practice, the distinction between shareholders’ and other stakeholders’ concerns may not be so clearly defined: Shareholders themselves are often employees, consumers, and residents in the communities where corporations operate. Consequently, as James...
Hawley and Andrew Williams argue in their 2000 study *The Rise of Fiduciary Capitalism*, shareholders may not be best served by the maximization of the share price alone and may be more concerned with a firm’s employment opportunities, quality of goods, and impact on the environment.

It is not clear which stakeholders will most benefit and what changes in corporate activities are likely to result when corporations acknowledge them. The outcomes could range from managerial opportunism, as Michael Jensen notes in his 2000 article “Value Maximization, Stakeholder Theory, and the Corporation Objective Function,” to economic democracy, as Paul Hirst suggests in his 1997 essay “From the Economic to the Political,” and anything in between these extremes. In any case, the concept of stakeholders greatly broadens the theorization of the corporation in terms of its governance, objectives, and conditions of existence.

**STALIN, JOSEPH**

**1878–1953**

Joseph Stalin (Ioseb Jughashvili) was born in the Georgian town of Gori on December 6, 1878. The son of a shoemaker, he rose through the Russian revolutionary movement to become the unchallenged leader of the Soviet Union. He adopted the name “Stalin” from the Russian word *stal*’ (steel) and advanced through the Bolshevik ranks after the movement’s leader, Vladimir Lenin, commissioned him to write a pamphlet titled *Marxism and the National Question* (1913). When the Bolsheviks seized power in October 1917, Stalin was named People’s Commissar of Nationalities. His rivalry with the head of the Red Army, Leon Trotsky, contributed to the growing fractures within the party. Just before a stroke incapacitated him in March 1923, Lenin fought with Stalin over the formation of the new Soviet Union, and he advised his comrades to remove Stalin from his post as General Secretary of the Communist Party. The other leaders did not heed Lenin’s warning, however, and most of them paid with their lives a decade and a half later.

Stalin accumulated enormous power within the party through his skillful political manipulation and his willingness to resort to ruthlessness. By the early 1930s he had defeated all of his rivals for power. During the “Stalin Revolution” of 1928 to 1932, the state forced millions of peasants onto collective farms, exiled or killed the most productive peasants (the so-called *kulaks*), and rapidly industrialized the economy. The height of Stalinist terror was reached in the Great Purges of 1937 and 1938, when approximately 700,000 people were executed and millions more were exiled, imprisoned, or died in labor camps.

Despite Stalin’s industrialization and militarization programs, the Soviet Union was not prepared for the German invasion of June 1941. Ultimately, the war was won by the tenacity and enormous sacrifice of the Soviet people, but Stalin provided inspiration for many, as well as the fear that one step backward would end in death. The Soviets lost some twenty-seven million people, but in the end the triumph over fascism provided the Communists with a new source of legitimation, and Stalin emerged with a new, uncontested authority.

Stalin’s postwar policies were repressive at home and expansive abroad. While he sporadically used repression against individuals and groups and deported ethnic minorities from newly annexed territories, he did not engage in mass killing on the scale of 1937. In dealing with his former allies during the cold war, Stalin attempted to maintain the Grand Alliance with the Western Great Powers while maintaining a sphere of influence in Eastern Europe, where he could impose “friendly” governments. Western leaders refused to acquiesce in the expansion of Soviet influence, and the cooperation of the war years disintegrated into two hostile camps, each armed with atomic weapons.

In his last years, Stalin was enfeebled by strokes, and he deteriorated physically and mentally. His growing isolation, arbitrariness, and inactivity affected the entire country. The ruling elite engaged in plots and intrigues, while Stalin threatened his closest associates. He died of a massive stroke on March 5, 1953.

STALINISM

What is Stalinism? It is not the same as Communism. For if all Communist regimes were Stalinistic, how could one distinguish between Joseph Stalin’s (1879–1953) mass terror, his annihilation policy, and the authoritarian Communist dictatorships in the Soviet Union and Eastern Europe after 1953? It is important to define the concept of Stalinism precisely, so that it can be clearly demarcated from other terms.

Several contemporaries observed that the Communist dictatorship in the Soviet Union of the 1930s and 1940s was different from other authoritarian dictatorships. Rather, it resembled the National Socialist regime in Germany, for it was characteristic of Bolshevik rule in the Stalin era to assert its claims to subdue the societies of the multiethnic empire, to dominate and control them. The Bolsheviks were trying to create new people and new orders from nothing, annihilating those they perceived as enemies of their new social order. The Bolsheviks allocated their enemies into social and ethnic groups, which were later to be isolated and annihilated. Already in the course of the civil war between 1918 and 1924, the Bolsheviks tried to stigmatize and annihilate ostensible class enemies. From 1929 to 1933 more than two million peasants were registered as kulaks (better-off farmers) and deported to Siberia, and more than ten thousand of them were killed. Former czarist elites and members of national minority groups suffered a similar fate. In 1937 and 1938 over a million people were arrested on Stalin’s order; some of them were shot according to quotas. More than 680,000 people found their death simply because they belonged to a social or a national group that the leadership imagined to be on the side of its enemies.

The terror was not only directed against the subjects of the regime; it also destroyed the party and the political elites of the Soviet state. After the end of World War II (1939–1945), the violence and terror were directed primarily against ethnic minorities, collaborators, and former Soviet soldiers who had been in German captivity. Therefore, one can say that Stalinism was a regime of terror, violence, and annihilation. It started with the rise of Stalin as an autocrat and ended with his death in 1953.

The first people to speak about Stalinism were its contemporaries. Leon Trotsky (1879–1940), who lost the struggle for power to Stalin in the 1920s, interpreted Stalinism as the rule of a bureaucratic caste that had replaced the proletariat. In this view, Stalinism was a betrayal of the principles of “true” socialism, allegedly represented by Vladimir Lenin (1870–1924). This interpretation, however, could not explain why the party and the state apparatus would destroy themselves in the late 1930s; furthermore, it offered no explanation for the role of Stalin in Stalinism.

Hannah Arendt (1906–1975) and Carl J. Friedrich (1901–1984) were also influenced by the idea of the modern dictatorship of the twentieth century. They claimed that Stalinism was a form of totalitarian dictatorship, thus differentiating it from other traditional authoritarian dictatorships. According to this theory, Stalinism was a totalitarian dictatorship because it claimed total dominance, led to the disintegration and transformation of the society, subjected the society to total control, and atomized and effaced the individual as a subject. It has been argued that this interpretation mistook the claims of the regime for reality and assumed that the Stalinist state was capable of exercising total control over the society. Revisionists in American historiography claimed, in their turn, that the repressive potential of Stalinism resulted from the dynamics of a “society in motion.” According to this concept, Stalinism was a result of the activity “from below” of competing groups within the power apparatus, which created social pressures to which the leadership had to respond.

After the opening of the Russian archives in the 1990s, the discussion about Stalinism took a new turn. There can be no further doubt that it was Stalin and his retinue who designed the strategies of mass terror and annihilation, although they could not consistently control the execution of those “policies.” The origin of Stalinism was the desire of the leadership to transform the society and subject it to total control. In this respect, Stalinism was totalitarian in its claim. But the Bolsheviks only disposed of a weak state and thus were not capable of realizing their demands in a heterogeneous multinational empire. This was the reason they exercised violence to break resistance. Terror and annihilation occurred, how-
ever, under the conditions of premodern, personified power structures. Not only did these power structures make possible the rise of Stalin to the head of the party, they were also a prerequisite for a system in which a despot like Stalin could realize his violent fantasies. Stalinism bears the name of Stalin, who was the embodiment of the system; it is not possible to discuss Stalinism without considering Stalin himself.

STANDARD CROSS-CULTURAL SAMPLE

The Standard Cross-Cultural Sample, or SCCS (Murdock and White 1969), is a cumulative and collaborative database of coded variables on maximally diverse and ethnographically best-described societies used by scholars in the social sciences. The champion of modern cross-cultural and statistical methods, George P. Murdock, in preparation for a standard sample, had classified the 1,267 societies in his coded Ethnographic Atlas into 200 distinctive world cultural provinces (Murdock 1962–1967, 1968). Douglas R. White (1968) had compiled a database of coded cross-cultural studies and done a concordance of previous samples (repeated by Ember 1992) that showed the fruitlessness of testing hypotheses that involved variables from different studies because there was little overlap between randomly drawn or ad hoc samples. White (1969), linked to the Columbia-Michigan historical-evolutionary successor to the Boasian school, had just completed the first comparative historical study to use Murdock’s Ethnographic Atlas codes in a regional study. The dual-authored approach to the SCCS signified a rapprochement between the Yale school of evolutionary functionalism and the historical anthropological schools at Columbia, Michigan, and Berkeley. Their founding of the Cumulative Cross-Cultural Coding Center (CCCCC) for the SCCS at the University of Pittsburgh (1968–1973), like their 1969 authorship, was coequal, although they were born nearly fifty years apart.

Both Murdock and White (1969) were advocates of multiple competing hypotheses (Chamberlain 1897). They designed the SCCS to be sufficiently large to test multivariate and competing hypotheses and sufficiently small to allow different investigators to code all the cases and so contribute to a cumulative database. Their evaluation of the literature on the 1,267 Ethnographic Atlas societies and other ethnographies led to their selection of the best and preferably earliest described representatives for 186 of Murdock’s cultural provinces that were most independent of one another. Each society was pinpointed to specific dates and communities (White and Murdock 2006). Bibliographic recommendations for ethnographic sources (White 1986) were classified by focus and pertinence. The SCCS—the goal of which was to represent the cultural diversity of well-described human societies—ranges from contemporary hunter-gatherers such as the Kung to historical cities (e.g., Babylon, 1750 BCE; Rome, 110 CE; the Khmer capital of Angkor, 1292; Erevan, 1880; Abomey 1890) to communities of industrial nations (e.g., an Irish village, 1932; a Russian commune, 1955).

Construction of the SCCS reflected Murdock and White’s concerns for sorting out alternative hypotheses. Correlations among variables in the SCCS cannot be taken as necessarily causal or functional relationships. As with similarities between the SCCS societies, they are affected by many factors, and the challenge is to separate out the different strands of influence, including measurement biases that may be studied by data quality controls (Naroll 1962; Whyte 1978b). Correlations or similarities may be influenced by functional associations, diffusion or borrowing from one society to another, or shared characteristics passed along through common ancestry. It is only the assumption of parallel independent inventions that supports the interpretation of a correlation between traits as functional adhesions in cultural systems. Murdock (1956), Harold E. Driver (1956), White (1968, 1975), and many other social scientists have long recognized the complementarities of different processes and the problems of inferences from correlational tests. History and science are integrally connected in this respect (Lyman and O’Brien 2004). The interpretation of intersocietal similar-
ities and correlational analysis and of comparative distributional findings necessarily involves the different kinds of networks that mediate the effects of diffusion or borrowing on correlations or similarities: Intermarriage, migration, economic exchange, political, and other interactions may be involved. Likewise, shared “ancestry” may include common “stock” that is linguistic, political, or the result of outmigration or genetic origin, such as mitochondrial genes passed entirely through the maternal line, which have strong adaptive correlates to environment (Mishmar et al. 2003). A similar principle applies to strictly paternal genetic origin passing through the Y chromosome. Assortative genes also may be implicated in selection for correlates or similarities. Without large samples of cases, such as the SCCS, or even larger, such as Murdock’s Ethnographic Atlas, the data are likely to be insufficient to separate or tease out different kinds of effects. From a statistician’s point of view, many of the alternative kinds of effects fall under the general term of historical nonindependence of cases. Only one major attempt has been made so far, however, to implement a diachronic coding of variables such as those studied by Eric Wolf (1982), but there is no intrinsic constraint against doing so for researchers ambitious enough to try. Such an approach would remedy the defect of using the SCCS exclusively for a synchronic or snapshot approach to comparison rather than coding changes over time at spatially pinpointed and related sites.

Edward B. Tylor, although very familiar with diffusion and issues of common ancestry, was rightly criticized for asserting that cross-cultural correlations represented functional evolutionary parallelisms in how traits are linked. Following Tylor’s 1889 paper, statistician Francis Galton objected that because his cases were not historically independent, Tylor was not warranted to apply the usual tests of statistical significance to his correlational results. This is because when duplicates of the same originals are included in a sample (which does not necessarily change correlations, since that would depend on which kinds of cases are duplicated), the variance among the originals is much greater than it would appear from computing ordinary standard deviations. Variance is an average, divided by the number of cases, and so the variance increases in dividing the observed deviations by a smaller number of originals. The statistical significance of any correlation so affected is diminished accordingly. This critique, however, allows for a sample-size adjustment to recompute the effective variance for a smaller estimated number of independent cases. All this was well understood in the 1880s. In the 1889 oral discussion, H. W. Flower made an additional important comment: that any cross-cultural method “depended entirely upon the units of comparison being of equivalent value” (Tylor 1889, p. 272) as, for example, the contrast between individual communities and larger religious, political, or regional units. The Galton and Flower problems may be linked in that if the traits of the smaller communities reflect those of the larger units, then the statistical significance of correlations of traits for the communities must be adjusted by reducing the effective n (estimated number of independent cases) to those of the larger units.

Galton’s problem, as named by Raoul Naroll (1961)—that is, the problem of historically nonindependent cases—is not limited to cross-cultural research. It entails foundational statistical problems endemic to non-experimental research in which the variance of statistics is underestimated when common historical factors or network interactions influence similarities of cases. Samples with historically nonindependent cases can still yield unbiased statistics (means and correlations, for example), but incorrect variance estimates of statistical estimates (and thus significance tests) require appropriate adjustment for Galton’s problem, independently of the question of how to interpret statistics in the light of alternative hypothesis. Random sampling provides no escape.

There remains an unfortunate Tylorian tendency in cross-cultural research today, however, to try to interpret cross-cultural correlations as evidence of functional associations among traits if the sample is both small and random. Carol R. Ember and Melvin Ember (1998), for example, incorrectly argue that the independence of cases is strictly a matter of independent selection of cases in the sample, as if historical independence did not matter. This view (1998, p. 678)—that “independence of cases means only that the choice of one case is not influenced by the choice of any other case (which random sampling guarantees)”—is fundamentally mistaken. Simple random or cluster sampling of one or multiple cases from a sampling frame of well-described societies (e.g., Naroll 1967; Lagacé 1979) does not solve nonindependence problems. Nor does it solve the problem of representation of diversity where data for comparable descriptive coverage are lacking for the vast majority of cases in the underlying universe, as in cross-cultural research. The mistaken view that random sampling solves Galton’s problem by guarding against sampling bias ignores the real problems, those of variance underestimates that skew significance and other tests in favor of the theory being tested. Malcolm Dow (1993) discusses the effects of ignoring Galton’s problem on unwarranted saving of incorrect hypotheses, and shows that appropriate statistical controls can also help identify results that would otherwise be rejected. Without appropriate variance estimates, two independent tests of the same correct hypothesis can easily fail to replicate if confidence limits are underestimated.

Some researchers now refer to nonindependence of cases as “Galton’s Opportunity” (Witkowski 1974) or
“Galton’s Asset” (Korotayev and de Munck 2003) because historical nonindependence and network interactions invite further research into alternative hypotheses. More recently, cultural anthropologists have used the SCCS, along with methods from evolutionary biology, to address common historical ancestry, horizontal transmission, environmental adaptation, and functional interrelations in the distributions of cultural traits (Mace and Pagel 1994; Borgerhoff Mulder et al., 2001). Methods of independent contrasts (Nunn, Borgerhoff Mulder, and Langley 2006), for example, are sensitive to even small amounts of horizontal transmission in cultural datasets.

The SCCS was designed to provide some of the appropriate measurements for Galton’s problem controls and for adjusting estimates of variance and significance tests accordingly. Murdock and White (1969) provided simple tests, following those proposed by Naroll (1961, 1965), to detect similarities among societies that depended on their relative geographic closeness and overall cultural affinities. They also provided a provisional phylogenetic language classification to help detect one of the types of common origin that might account for similarities among nonindependent cases. These allowed for estimates of the effective sample size of different variables. Benefits could increase for multivariate analysis if some of the new coding studies would expand ethnographic coverage to a new Extended SCCS, yet to be designed, with double the number of cases.

Hundreds of cross-cultural studies have by now contributed new codes for the pinpointed societies in the SCCS. Those resulting from Murdock and White’s 1968–1973 CCCC research projects are published along with others in Barry and Schlegel (1980). The thousands of authors who have used SCCS data for their research cover virtually every area in which cross-ethnographic comparisons are useful, including a great many subdisciplines of the social and related sciences. Assuming that a researcher avoids spurious findings that result from mistaken strategies such as cherry-picking high correlations and significance or ignoring Galton-type problems and opportunities, cumulativity can have exponential benefits when researchers, typically coding thirty or more new variables, can test relationships in a database with thousands of variables.

A sample of some findings of authors who treat their subject comprehensively at book length, using the SCCS, and who added coded data on their specialties, will illustrate how the SCCS is sufficiently large to test multivariate hypotheses. Sociologist Orlando Patterson (1982) carried out a magisterial study of the internal dynamics of slavery based on his own codings of slavery variables for the sixty-six slave societies in the SCCS. This was a first-of-its-kind study on the nature of slavery over time, world and historical-comparative in scope: tribal, ancient, premodern, and modern. Slavery is shown to be “a parasitic relationship between master and slave, invariably entailing the violent domination of a natally alienated, or socially dead, person,” and its internal dynamics to involve “a single process of recruitment, incorporation on the margin of society, and eventual manumission or death.”

Economist Fred Pryor (2005a) carried out a similarly broad program of research in his comparative study of world economic systems. In his article (2005b) on the forty-one agricultural societies in the SCCS, he used clustering analysis of variables to cover a full range of variation in production, property, and distribution. He found evidence for only four basic agricultural systems among thirty-six clusterable cases and apart from the five that were unclusterable: herding plus, egalitarian farming, individualized, and semimachinery farming. Although “many anthropologists and historians consider agricultural systems to be the outcome of environmental, social, social-structural, and political variables, a statistical analysis indicates that very few such variables are correlated with the derived economic systems. The systems are thus revealed to stand as independent entities and worthy of more intensive study” (2005b, p. 2).

Anthropologist and Islamic specialist Andrey Korotayev (2004) was the first to code world religion for the SCCS. Two of the most powerful of his fertile set of findings are that world religion is the best predictor of large regional similarities in social structure, and that many of the major types of social structure (like Pryor, identified by a cluster analysis on the relevant variables) closely follow enduring regional boundaries such as the extent of the eighth-century caliphates resulting from the Arab/Islamic expansion.

Karen Paige and Jeffrey Paige (1981), teamed as sociologist and political scientist, succeeded in identifying systemic patterns in their study of gender roles by restricting their focus to the 108 prestate societies in the SCCS. They sharpened their hypotheses to focus on three determinative levels of resources: low-value, unstable, and stable. The hypotheses they tested showed how resource levels affect women and the womanly interests of men either in identification with females or in surveillance over female reproduction. With low material resources, females tend to be food producers and highly valued for the reproduction of children who add labor and enlarge the kin group and its prestige. With stable resources, property and inheritance become major issues for men as regards women: Children’s paternity comes to be at stake, and men often form conflicting fraternal interest groups. The findings of these authors show high coherence with respect to their theory of the politics of reproductive issues and the effects of these issues on social organization generally.
Evolutionary biologist Laura Betzig (1986) focused on the starkest of Darwinian issues, power and the differential extremes of open or sub rosa control over female reproduction in harems and among concubines and mistresses, as documented by her coding of the 186 cases in the SCCS. Like Paige and Paige, she regarded men in societies with property as strongly concerned with the fidelity of their wives, but she went further to explore the vicious circle of links between differences in power and differences in reproductive success that are virtually without limit for the most powerful males in the historical era. Controversial and starkly sociobiological, her explanation as to why modern states become less despotic is that to attract mercenaries, specialists in defense, craftsmen, and those who run the state, people in power are forced to make concessions to others who still serve, directly or indirectly, to contribute to the reproductive efforts of men in power. Her philosophical predilection is to reject theories of further checks and balances in favor of an extreme: that the powerful dictate the laws in their own (reproductive) interests even in the absence of absolutist despotism.

Peggy Sanday (1981), exploring feminist issues, rejected arguments of universal female subordination, and after coding variables for different measures of relative male domination and female power, argued that dominance is not inherent in human relations but is socially constructed through deep symbolic mechanisms and not only as instituted in a people’s secular power roles and behavior. Symbolic sources of male dominance, she argued, derive partly from ancient concepts of power, as exemplified by origin myths. Her hypotheses were designed to test the extent to which female power and male dominance are further determined by a people’s adaptation to their environment, social conflict, and emotional stress. She illustrated her thesis through case studies of the effects of European colonialism, migration, and food stress, supported by statistical associations between aspects of sexual inequality and diverse forms of cultural stress.

The advantage of a database like SCCS is that, in spite of what theories authors are hoping to test, in so doing they contribute coded data and statistical hypothesis tests that can be revisited and challenged by others, using new data and that cumulated from the past. Some researchers are intent on coding variables that reflect the range of variability in the phenomena they study and on working more inductively from their findings, guided by theoretical questions. An example of a strongly inductive approach is that of Martin K. Whyte, who instructed his researchers to code half the SCCS societies for each of hundreds of gender-related variables relevant to the literature on gender roles. He summarized how his findings on male dominance contrast with those of Sanday, noting that his variables have divergent cross-cultural distributions. Some, such as items for political leadership, are highly skewed in favor of men; others, such as property inheritance…, are more moderately skewed toward men; still others, such as the elaborateness of funerals or final authority over infants, show little or no male bias cross-culturally… [Further], these different indicators are not associated with each other… [and] some things that have been assumed in the … literature to have status implications for women may not. For example, there now seem to be no grounds for assuming that the relative subsistence contribution of women has any general status implications. (Whyte 1978a, p. 169)

Many of these authors address the Galton problem of controlling for nonindependence of cases. How prevalent is autocorrelation among the variables studied in cross-cultural research? Econometrician Anthon Eff (2004) tested 1,700 variables in the SCCS database to measure Moran’s I for spatial autocorrelation (distance), linguistic autocorrelation (common descent), and autocorrelation in cultural complexity (mainline evolution). “The results suggest that … it would be prudent to test for spatial and phylogenetic autocorrelation when conducting regression analyses with the Standard Cross-Cultural Sample” (Eff 2004, p. 153). He illustrated the use of autocorrelation tests in exploratory data analysis, showing how all variables in a given study can be evaluated for nonindependence of cases in terms of distance, language, and cultural complexity. He explains the methods for estimating these autocorrelation effects, illustrates ordinary least squares regression using the Moran I significance measure of autocorrelation (options for Durbin-Watson tests are commonly available as an alternative), and shows how, when autocorrelation is present, it can often be removed so as to get proper estimates of regression coefficients and their variances. This is done by constructing a respecified dependent variable “lagged” by weightings on the dependent variable on other locations, where the weights are degree of relationship. Ordinary least squares regression will still bias the estimated coefficients when the dependent variable is respecified, but maximum likelihood methods (Anselin 1988) will give unbiased statistics and variances in which the effects of autocorrelation have been removed.

Use of the SCCS seems to encourage good research practices. Other methodological advances that would not have been made without the shared SCCS database include statistical entailment analysis, for example, of the sexual division of labor (White, Burton, and Brudner 1977; White 2000) and Murdock’s (1980) use of this discrete-structure statistical method in his study of cultural theories of illness and their sociological entailments.
All of the cross-cultural articles and data published in the journal *Ethnology* for the SCCS and all the bibliographic, pinpointing, and coded data sets of the SCCS are in the public domain so as to facilitate scientific research. The journal *World Cultures*, edited by White from 1985 to 1990, has continued to publish SCCS cross-cultural codes and analytical articles. Google Scholar as of 2006 cites 413 online citations to articles referencing the SCCS, and the number unreferenced is perhaps four to six times that estimate. These works address a huge variety of topics. Their diversity, and their common references to a framework of variables and sample cases, along with the agreements and relatively clear bases for disagreements among authors, can be taken as indicators of success in the research design and cumulativity of the SCCS.

The SCCS is not about statistics or method but about science, and about broadly encompassing anthropological-cum-historical science that encompasses contending and often complementary theories of the social, biological, and physical sciences as they interact with questions about human societies and culture. The SCCS does not represent a narrowly conceived school of thought about what the assumptions or methods of this science ought to be, other than a good and far-ranging combination of science, history, and humanities. If one draws today from new findings about mitochondrial inheritance of energetic-environmentally adaptive genes in the maternal line, for example, and reconstructs the human matri-line in its geographic migrations (and similarly for the Y chromosome patriline), is the SCCS a place to try to develop approaches to understanding the complexities and testing hypotheses about how human evolution has proceeded to the present? Or, taking Wolf’s (1982) approach to world sociopolitical comparisons through a diachronic lens of world system histories and interactions: Is the SCCS not a suitable sample for entirely different kinds of codes that compare what is known about these societies through time, and through networks of interaction, not with one another but with larger entities of the global system and through the larger networks of sociopolitical and military interactions?

Recognizing that “each society is a process in time” (quoting Edmund Leach), Robert McC. Adams (2004 p, 353) reviews the vexing problems of using a mix of textual sources and archaeological data in coding or process modeling. To code or comprehend through space and time, however, also involves attention to the subjective positioning of the different texts that provide perspectives on history, and so opens into a whole set of other classical problems in anthropology that remain to be successfully integrated—at the level of the individual investigator, the research team, or a larger and more cumulative enterprise. Part of the success of the SCCS collectivity of researchers in relation to those who publish the data from investiga-

tors and from difference sources is not to try to edit out or reedit data but to respect the integrity of original data in correct form as originally presented from a particular standpoint. Thus different streams of data coming from different sources and investigators are not compromised. Rather these independent streams themselves can be compared for indicators of what might be missing, hinted at, biased, or interpreted as reliable through cross-validation and triangulation of methods of analysis.

Mindful of Flower’s observation that any cross-cultural method depends entirely on the units of comparison and the problem under study, Murdock and White did not regard the SCCS as a unique touchstone for theory testing but only as a worthy example of what could be accomplished with collaborative construction of shared databases and efforts at comparable codings from ethnographic materials to facilitate new understandings in the human sciences.

STANDARD DEVIATION

The standard deviation is found throughout the behavioral and social science literature. It is the average spread among a set of scores around their mean, and it is the most frequently used measure of variability in parametric datasets. Researchers analyze their data by looking at the variability and breaking that variability down into its component parts.

When we describe any set of data we use three characteristics: (1) the form of the distribution, (2) the mean or central tendency, and (3) the variability. All three are required, since they are generally independent of each other. In other words, knowing the mean tells us nothing of the variability.

Variability is a characteristic of all measures. In the social sciences, the people or groups that researchers study may be exposed to the same treatment or conditions, yet they show different responses to that treatment or condition. In other words, all the scores of the people or groups would be different. The goal of the scientist is to explain why the scores are different. If everyone were exactly the same, the standard deviation would be zero.

In addition to describing their data, researchers use the standard deviation in inferential statistics. When they manipulate conditions or treatments, researchers attempt to explain different scores between groups by looking at the variability between the groups. If the groups are different enough, then they are said to be statistically significantly different. This conclusion may be drawn based on the probability (odds) that the difference could have occurred by chance. Researchers use these samples as estimates of the true parameters in the population of interest, and the standard deviation is used (along with the sample size) to establish the precision of the estimates (Winer 1971). The smaller the standard deviation, the smaller the error (or the greater the precision of the estimate).

We also find variability that cannot be explained by the treatments or conditions applied to the people or groups. This variability must also be a part of all the explanations. This part of the variability is often called error, since experiments or studies do not indicate why it occurs.

The English mathematician and statistician Karl Pearson (1857–1936) introduced the procedure and the term standard deviation to statistics in 1892 (Magnello 2005). The standard deviation calculation is very straightforward. The standard deviation is defined as the square root of the sum of the squared deviations from the mean, divided by the number of squared deviations. The equation for the standard deviation is

\[ \text{stddev} = \sqrt{\frac{\sum (X - M)^2}{N}} \]

where \( \text{stddev} \) is the standard deviation, \( X \) is a raw score, \( M \) is the mean of the scores, \( X - M \) represents the deviation of a score from the mean, and \( N \) is the number of scores. Many different symbols have been used to represent the elements of the equation, but in all cases the standard deviation is the square root of the average of the squared deviations from the mean.

At this point, new students of statistics often ask why researchers do not use the deviations from the mean directly. The deviations from the mean cannot be averaged since the sum of the deviations from the mean is always zero. It is possible to use the mean deviation score, which avoids the zero sum by employing absolute values, but this tends to be mathematically cumbersome (Weisstein 2003).

An example will illustrate the calculation of the standard deviation. Let us assume we have five scores for five individuals. The \( N \) is equal to 5. The scores are 10, 8, 6, 4, and 2. We must first calculate the mean, so we add all the scores and then divide by \( N \). The sum of the scores \( (10 + 8 + 6 + 4 + 2) \) is 30, and the mean is 30 divided by 5, or 6. Next we must subtract the mean from each score to get the deviation score \((10 - 6 = 4, 8 - 6 = 2, 6 - 6 = 0, 4 - 6 = -2, \text{and} 2 - 6 = -4)\). Note we cannot get the mean deviation score because the sum of the deviations is zero. This is always true. We solve this problem by squaring each deviation score (which eliminates the negative signs), then summing and dividing by \( N \) \( (4^2 = 16, 2^2 = 4, 0^2 = 0, -2^2 = 4, \text{and} -4^2 = 16)\); the sum of these deviation scores squared is 40; dividing 40 by 5 gives us 8). Since this result is the average of the squared deviations (also known as the variance), we must get back to the original score units by taking the square root of 8. The final result is a standard deviation of 2.8284 (rounded to four decimal places). We can say the average spread in the set of scores is about 2.8 (or as precise as we need to be).

A common way to help students and others visualize the standard deviation is to show a graph of a normal distribution, with the standard deviations as lines above and below the mean. We do this because many variables of interest to science are distributed normally (or approximately so) in the population of interest. In a large distribution (and a population), there are about three standard deviations above the mean, and three below the mean. Given these assumptions, we can say that approximately 68 percent of a population falls between \(-1\) and \(+1\) standard deviation of the normal curve; approximately 95 percent falls between \(-2\) and \(+2\) standard deviations; and better than 99 percent of the population falls between \(-3\) and \(+3\) standard deviations.

When the distribution of scores is not approximately normal, the use of the standard deviation, and the mean itself, may not be the preferred approach for describing the data. The reason for this is that extreme scores will have a large impact on the squared deviations from the mean, making the spread among scores appear quite large.
Skewed population data, such as income, may best be described using the median for central tendency and the mean absolute deviations from the median as the measure of spread. Another approach is to use the semi-interquartile range (also called the interquartile range) to describe the spread in skewed distributions. Extreme scores do not particularly affect this index, but it is more susceptible to sampling fluctuation and should not be used if the distribution is approximately normal. Box plots are often used to show both central tendency and dispersion using the semi-interquartile range. Unfortunately quartiles and box plots do not have the mathematical properties of the standard deviation and limit further analyses.

The standard deviation is used widely throughout the social sciences. In economics, the description of variations in stock prices employs the standard deviation. In political science, the assessment of voter preference is described as a percentage plus or minus, where the plus or minus amount is derived from the standard deviation. In psychology and sociology, variability among individuals and groups is routinely expressed in standard deviation units. In these days of powerful computer-based statistical tools that are available for laptop computers (arguably the two most widely used are SAS and SPSS), obtaining standard deviations (and most other statistical results) is quick and precise. Other programs, designed more for business use, also provide built-in formulas for calculating the standard deviation (often these are not considered accurate for scientific reporting).

**STANDARDIZATION**
**SEE** Modernism.

**STANDARDIZED TESTS**
Standardized testing as a gateway to higher education was first established in the United States with the development of the College Entrance Examination Board in 1900. This board created a test designed to standardize admissions to elite universities in the northeastern United States and to encourage the development of a common curriculum among elite boarding schools (Chandler 1999; Lemann 1999). The original test consisted of essays and was not designed for mass testing. The College Board, however, created a broader test of IQ in 1926, the Scholastic Aptitude Test, commonly known today as the SAT I. This test was intended to help elite schools identify high-achieving students in nonelite high schools. In the early years, it also distinguished between white-collar students who were suitable for college and blue-collar students presumed to be ill prepared for such an education (Blau et al. 2003). By the mid-1950s, the demand for college education soared, spawning the development of the American College Testing Program (currently known as the ACT) in 1959. This test is the main alternative to the SAT. The origins of the SAT and ACT clarify their differing approaches. The SAT test was originally based on Army IQ tests as a measure of intelligence, whereas the ACT was historically designed to measure achievement rather than intelligence or aptitude.

Despite these differences in intent, the tests are similar in structure. The SAT I (also known as the SAT Reasoning Test) is designed to measure students’ critical thinking and problem-solving skills. The test consists of three sections. The critical-reading section includes ques-
Standardized Tests

tions on analytical reading, reading comprehension, and sentence completion. The writing section evaluates students’ ability to write clearly, concisely, and competently. It also assesses students’ ability to critically assess sentence and paragraph structure, as well as grammar. Finally, the mathematics section includes questions covering algebra, geometry, statistics, and advanced data analysis.

The ACT is similar to the SAT, but it has four broad sections. The English section evaluates writing and rhetorical skills. The mathematics section includes questions on algebra, geometry, and trigonometry. The reading section measures reading comprehension. The science section tests scientific skills including reasoning, analysis, and problem solving. Finally, the writing section tests writing skills.

The SAT and ACT are widely utilized among students and colleges. In 2006 about 1.5 million high school seniors took the SAT and approximately 1.2 million students took the ACT. Most colleges accept either the SAT or ACT for admissions since standards for comparing these scores are easily accessible.

The importance to higher education of standardized testing persists into graduate school, but testing tools are more diverse for graduate admissions than for undergraduate admissions. Professional schools require standardized tests that emphasize skills required by their specific disciplines. These include the Law School Admission Test (LSAT), the Medical College Admission Test (MCAT), and the Graduate Management Admission Test (GMAT). A more general and widely used standardized testing tool is the Graduate Record Examination (GRE). In 2005 nearly 500,000 persons took the GRE, accounting for 35 percent of persons with bachelor’s degrees (National Center for Education Statistics 2006). The GRE has three sections. The verbal-reasoning section tests the respondent’s ability to recognize concepts and to analyze information and relationships among parts of sentences. The quantitative-reasoning section tests algebra, geometry, data analysis, and quantitative reasoning. Finally, the analytical-writing section assesses the respondent’s ability to write clearly, effectively, logically, coherently, and competently.

Key criticisms of standardized testing that have generated widespread sociological interest are: (1) the neglect of environmental differences among students, particularly those associated with cultural and racial differences; and (2) testing bias and validity. Criticisms of cultural and racial bias abound within the literature. One notable example is Tukufu Zuberi’s Thicker than Blood (2001). Zuberi contends that the IQ test, the predecessor of modern standardized testing, developed out of the eugenics movement. This movement was committed to identifying biological differences between the races and classes. Proponents posited that racial inequalities in society were biologically determined because whites were perceived to be genetically superior. According to Zuberi, IQ tests provided statistical support for eugenics because white students scored higher on these tests than black and immigrant students.

During this period, many scholars argued that IQ tests, which measured math and verbal skills, accurately reflected biological differences in intelligence. Scholars influenced by this tradition purport that differences in test scores between blacks and whites reflect inherent biological differences between the races (Herrnstein and Murray 1994). However, sufficient data have not been provided to support this hypothesis. Today, most scholars acknowledge that standardized testing is biased and reflects more than biological differences between students.

Christopher Jencks, an influential scholar in this debate, has identified multiple biases in standardized testing. First, he argues that standardized tests neglect environmental differences between students, which creates bias. Comparisons of scores among racial groups are problematic because the IQ test was originally designed to compare the mental ability of students who were raised in comparable environments with similar levels of educational opportunity. Yet mass testing neglects environmental differences between students. This proposition has received widespread empirical support. William Rodgers and William Spriggs (1996) offer one of the most methodologically sophisticated assessments of environmental background factors by showing that a consideration of family and educational background reduces racial differences in test scores. However, they also find that the impact of the environment on test scores varies by race. Furthermore, racial biases exist in the measurement of standardized tests because components of these tests have different long-term effects on individuals’ wages, depending on race and gender. Thus, Rodgers and Spriggs argue that standardized tests are racially biased because they measure different factors for different races.

Standardized tests are also biased in content (Jencks 1998). This is obvious when considering the language of the test. For students whose primary language is not English, standardized testing measures both English proficiency and scholastic achievement. As a result, these tests do not accurately reflect the achievement or readiness for college of language-minority students (LaCelle-Peterson 2000). Less-obvious content biases are prevalent in vocabulary words and essay topics.

Standardized tests are also biased methodologically if they claim (or are assumed) to measure ability because groups historically subjugated in society, including blacks, women, and the poor, are disadvantaged in this situation (Jencks 1998). Indeed, researchers have found that these tests create anxiety among African Americans and students of low socioeconomic status, who underperform on
tests perceived to measure intellectual ability (Croizet and Dutrevis 2004; Steele and Aronson 1998). Additionally, women underperform when gender stereotypes are made salient (Benbow 1988).

Judith Blau and colleagues argue that blacks and whites place different significance on achievement tests. Whites believe that these tests measure ability, while blacks perceive unfair discrimination in testing practices. Thus, they conclude that black students and their parents place less weight on standardized test scores when considering postsecondary educational goals. Blau finds that test scores are a better predictor of educational attainment for white students than for black students. Furthermore, low-scoring black students are more likely than low-scoring white students to pursue postsecondary education. Thus, low scores are more likely to discourage white students, suggesting cultural differences in the value placed on tests (Blau et al. 2003). Further research is needed to determine how Blau’s theory applies to gender and class issues. Preliminary research suggests that females place less value on mathematical portions of standardized test scores due to stereotype threats (Lesko and Corpus 2006).

Differences in the ability of standardized tests to predict future outcomes highlight an additional criticism of standardized testing: The tests are not valid because they are not accurate predictors of students’ success in college or graduate school (Jencks 1998). Indeed, many scholars have found that standardized test scores do not predict grade point average in college (Gandara and Lopez 1998; Fleming 2000, 2002) or in graduate school (Oldfield 1994, 1996), and they do not predict success in the labor market (Blackburn 2004; Rodgers and Spriggs 1996).

The effect of the debates on standardized testing is evident. The title of the SAT has changed multiple times from the Scholastic Aptitude Test (a test of ability) to the Scholastic Assessment Test (this more general term suggests that the test measures more than ability) and finally to simply the SAT. In addition, the College Board has altered testing questions on the SAT to reduce cultural bias introduced from disparate knowledge and interests between groups in society. Furthermore, it has cut sections of the test to reduce reliance on vocabulary and increase reliance on verbal problem-solving skills. Even with these changes, however, racial and gender disparities persist. In 2004 the average SAT verbal score was 508 for college-bound high school seniors, ranging from 430 for black seniors to 451 and 528 for Mexican American and white seniors, respectively. Similarly, mathematics scores ranged from an average of 427 for black students to 531 for white students. ACT scores also vary by race. Average English ACT scores were 20.4 in 2004, ranging from 17.2 for black students to 18.3 for Mexican-American students and 22.5 for white students (Freeman and Fox 2005).

The persistence of the race gap is attributable to differences in family background and educational opportunity. Black students are generally raised in families with fewer resources than white students. Indeed, according to Melvin Oliver and Thomas Shapiro (1995), 63 percent of black households have zero or negative financial assets, meaning that their debt outweighs their assets. Only 28 percent of white families have negative financial assets. Furthermore, white median net worth (defined as the sum of all assets minus debt) is nearly twelve times black median net worth. This has important implications for test scores because students raised in families with greater wealth have the financial resources to prepare for standardized testing and attend college. Indeed, parental wealth and education are the two most important predictors of college attendance (Conley 1999).

The racial gap in test scores also persists because black students have fewer opportunities to prepare for the test. Schooling in the United States is highly segregated by race and socioeconomic status. Roslyn Mickelson (2006) found that predominantly black schools offer fewer SAT prep courses than integrated or predominantly white schools. Furthermore, even when black and white students study in the same schools (i.e., in integrated schools), they are offered different educational opportunities because they are grouped into classes by ability. Black students are more likely to be assigned to “lower-ability” classes than white students with the same grades and test scores. These classes are often taught by less-experienced teachers, and the courses offer a more general education rather than a college-preparatory education. Thus socioeconomic resources and educational opportunities explain the existing gap in standardized test scores by race.

As for gender, the standardized test score disparity is not uniform. Historically, boys and girls had equivalent verbal scores, but boys scored higher in math (Benbow 1988). The math score gap has diminished over time, in part because girls’ educational opportunities have expanded, and they are taking more advanced math courses in high school. In 2004 boys and girls scored 538 and 504, respectively, on the math section of the SAT. Much of this remaining gender gap in test scores develops during high school because women continue to study in less rigorous math courses, and they are less likely than boys to participate in mathematically oriented extracurricular activities (Leahey and Guo 2001; Pallas and Alexander 1983; Vogt Yuan 2005).

It is important to understand what standardized tests measure because standardized testing has gained national recognition with the passage of the No Child Left Behind Act in 2002. This policy initiative requires standardized testing for students in the third through eighth grades and at least once during high school. The primary goal of the
legislation is to reduce achievement gaps between students, particularly by race, poverty status, disability, ethnicity, and English proficiency. This act magnifies the significance of standardized testing. By neglecting the impacts of the environmental differences, testing biases, and validity issues discussed here, standardized testing will be of limited use to educators and policymakers as they seek to close achievement gaps.

STAR TREK
Although not popular during its original run in the late 1960s—it was cancelled after three low-rated seasons—the television program Star Trek developed a cult following that is still vibrant forty years later. Over the years, fans have appreciated the Star Trek saga’s compelling stories and characters, idealistic and progressive view of the future, and confrontation with relevant political and cultural issues.

Gene Roddenberry created Star Trek, and the NBC network launched it in September 1966. The show centered on the twenty-third-century pangalactic travels of the USS Enterprise, the flagship of Starfleet—the military sector of the United Federation of Planets. The composition of the Enterprise crew itself was a social commentary on the advancements in civil rights and the nascent, albeit modest, recognition of gender equality. The ship was commanded by a white male, Captain James T. Kirk (William Shatner), but his supporting crew was considerably more diverse than the casts of other contemporary television shows. Using the fictional Star Trek universe, the show’s episodes addressed the controversial issues of the late 1960s, including the Vietnam War, the cold war, and race relations. The show also broke new ground, most notably in featuring the first televised interracial kiss.

Despite Star Trek’s critical success, NBC cancelled it in 1969 because of low ratings.

Cancellation after only three seasons would be the death knell for most television programs, but Star Trek’s cancellation marked only the beginning of one of the most successful science fiction ventures ever. Almost immediately, Star Trek reruns aired in syndication, earning high ratings and drawing new fans, known as “Trekkies” or “Trekkers.” This fan base grew larger and more organized, and in 1972 Trekkies began holding Star Trek conventions. The show’s actors, writers, and producers, along with thousands of fans, attend these conventions to discuss Star Trek, to trade memorabilia, and to socialize. With this demonstrable level of support, in 1979 Paramount Studios released a movie, Star Trek: The Motion Picture, which was produced by Roddenberry. The movie reunited the original cast, and it allowed the Star Trek legacy to continue. Throughout the 1980s subsequent Star Trek movies tackled social issues; for example, Star Trek IV: The Voyage Home (1986) was a parable on environmentalism and species protection.

Star Trek’s increasing popularity gave Roddenberry the opportunity to create a new television program, Star Trek: The Next Generation, which debuted in September 1987. The Next Generation featured the twenty-fourth-century crew of the Enterprise, commanded by Captain Jean-Luc Picard (Patrick Stewart). As with the original Star Trek series, The Next Generation addressed important political, cultural, and social issues of its time. Anticipating the end of the cold war, the United Federation of Planets made a lasting, albeit tenuous, peace with its former archrivals the Klingons. In addition, The Next Generation reflected advancements in gender equality that had been achieved since the 1960s; whereas the original series relegated women to supporting roles, women in The Next Generation served as ships’ doctors, security chiefs, and even admirals. The Next Generation episodes also addressed sexual orientation, the struggles of subjugated peoples, and ethical issues concerning animal experimentation. Unlike the original series, The Next Generation was well funded and highly rated, and it aired for seven seasons. Gene Roddenberry died in 1991 and did not see the full run of The Next Generation, but others ensured that the Star Trek legacy would continue.

The Next Generation’s success led to more movies during the 1990s featuring the cast of The Next Generation. By 2006 there had been ten Star Trek movies. Additionally, The Next Generation’s success spawned two more television series: Star Trek: Deep Space Nine (1993–1999) and Star Trek: Voyager (1995–2001). Neither show took place on the Enterprise, but each continued with the basic Star Trek themes; for example, at a time when few television programs featured women in charge, a woman commanded the Voyager ship. In 2001 yet another Star Trek series, Star Trek: Enterprise (2001–2005), was launched. This show took place in the twenty-second century, during the early years of the Enterprise and Earth’s entry into the United Federation of Planets. Low ratings and less popularity among fans brought the cancellation of Enterprise in 2005. Although to date there are no more television programs planned, Star Trek remains part of the American cultural lexicon, with academics using the show as a vehicle for their social criticism (e.g., Johnston 2002; Roberts 1999). Reruns of the television programs and movies remain popular, and Star Trek conventions are still held worldwide.

Steven Tauber
**STAR WARS**

George Lucas’s film *Star Wars* (1977) had a lasting impact on the genre of science fiction films, the film industry in general, popular culture, and the political culture during and after Ronald Reagan’s presidency. Lucas had established Lucasfilm Ltd. in 1971 and later founded Industrial Light and Magic, a special effects company. The revolutionary special effects in Lucas’s films set a standard for future science fiction and action films. The new technologies used to make *Star Wars* included a new type of motion camera, innovations in sound technology, and developments in digital and computerized sequencing.

Before *Star Wars*, possibly the last science fiction film to revolutionize the genre was director Stanley Kubrick’s 2001: A Space Odyssey (1968). The financial success of *Star Wars* changed Hollywood’s negative perception of science fiction films, making possible the production of other such films, including *Star Trek: The Motion Picture* (dir. Robert Wise, 1979).

Lucas eventually made six *Star Wars* films, the original trilogy and a prequel trilogy. The titles and years of release are: *Star Wars* (later retitled *Star Wars: Episode IV–A New Hope*, 1977); *Star Wars: Episode V–The Empire Strikes Back* (1980); *Star Wars: Episode VI–Return of the Jedi* (1983); *Star Wars: Episode I–The Phantom Menace* (1999); *Star Wars: Episode II–Attack of the Clones* (2002); and *Star Wars: Episode III–Revenge of the Sith* (2005). By 2005 the two *Star Wars* trilogies and all merchandising and franchising had earned close to $20 billion, making it among the most popular and profitable film series in U.S. film history. Many of the episodes were nominated for and won Oscars and other film awards.

The plot of the films centers around Luke Skywalker, his family, the Jedi Knights, and the turbulent history of an intergalactic empire struggling from opposing totalitarian and democratic forces. Luke’s character, his independent spirit, and tensions between him and his father (and surrogate fathers) hearken back to stories from the American West, Dickensian tales, and chivalry and medieval romances. The films also embody Joseph Campbell’s structuralist approach to mythology. A subtext underlying the films pits a romantic notion of mysticism and the divine in nature against an overreliance on technology. Though futuristic and featuring such “technology” as light sabers, warp drives, androids, and sky cities, the story takes place “a long time ago in a galaxy far, far away,” a setting that shrouds *Star Wars* in an ambiance of legend and mythology. In technical terms, the films are more science fantasy than science fiction and created a genre labeled “space opera.”

A variety of influences have been identified. These include Japanese director Akira Kurosawa’s *The Hidden Fortress* (1958); author Isaac Asimov’s *Foundation* trilogy (1951–1953); Frank Herbert’s *Dune* books; and Jack Kirby’s *Fourth World* series published by DC Comics in the early 1970s. The relationship between Luke and his Jedi mentor Yoda is reminiscent of author Carlos Casteneda’s *Don Juan* books about shamanistic initiation. The films’ opening credits, with a scrolling tilted text that moves outward, is an homage to the *Flash Gordon* cinematic serials from the late 1930s. Lucas indicated that he wanted to create a modern mythology, and the popularity of the films suggests that he succeeded. As evidence of this popularity are the many *Star Wars*-themed books and novelizations, comic books, syndicated comic strips, video and computer games, Web pages, and blogs, in addition to action figures and other *Star Wars*-related franchising and merchandizing.

Perhaps the most striking influence of Lucas’s films was on American political culture during and after the Reagan administration (1981–1989). Reagan was at times dubbed “Ronald Ray-Gun” in underground comic strips from the 1960s because, as an actor, he had played Steve Coe in Lewis Seiler’s *Murder in the Air* (1940). In this film, Reagan’s Coe tests an experimental “ray” weapon called the Inertia Projector. Reagan was reportedly a fan of *Star Wars*, and he incorporated various allusions to the film into his foreign policy. In particular, he referred to the Soviet Union as the “Evil Empire,” advocated a missile defense system that was later labeled “Star Wars,” and drew parallels between communism and the Rebel Alliance of *Star Wars*.

Reagan’s two Evil Empire speeches were delivered on June 8, 1982, at the British House of Commons and on March 8, 1983, to the National Association of Evangelicals. On March 23, 1983, Reagan delivered what became known as the “Star Wars speech,” in which he enjoined “the scientific community … those who gave us nuclear weapons … to give us the means of rendering these nuclear weapons impotent and obsolete.” Reagan’s Strategic Defense Initiative, which proposed the development of ground- and satellite-based laser weapons that could target and destroy ballistic missiles, was termed “Star Wars” by a skeptical press and scientific community. The program was seen as heightening cold war tensions and militarizing space.

*Star Wars* allusions continued during the George H. W. Bush and George W. Bush administrations. During the Persian Gulf War (1991), for example, military officials called themselves Jedi Knights. Research, development, and funding for “Star Wars” missile defense technology continued through 2006, generating several books, including Francis FitzGerald’s *Way Out There in the Blue: Reagan, Star Wars, and the End of the Cold War* (2000); *The Phantom Defense: America’s Pursuit of the Star Wars Illusion* (2001) by Craig Eisendrath, Melvin A.

### STARE, THE

The ancient Greeks explored the dialectics of the gaze in the form of the myth of Medusa, who can turn people to stone with a single glance. The Medusan story symbolically condenses a range of experiences of looking and being looked at in the graphic image of the “petrifying gaze” (*petrification* meaning literally the turning of the other into an inert object), and the Medusa, being a female deity, introduces the idea that “looking” implicates sexual and gendered phenomena of some social and cultural importance.

The human sciences have demonstrated that “looking” is a profoundly social and political phenomenon that obliges the analyst to distinguish between different modalities and practices of seeing (“looking,” “gazing,” “staring,” “glancing,” and so forth). It is thus important to distinguish the physical and physiological properties of “seeing” from the culturally defined forms of “looking.” For example, very young infants tend to stare at objects and others (particularly other persons with a distinctive physical attribute); as children are socialized they learn to sublimate this natural inclination into the more civil act of glancing and looking away. Children are taught that certain forms of eye contact are regarded as impolite, that looking is subject to appropriateness norms.

We are not far from Jean-Paul Sartre’s analysis of voyeurism and the attendant social relations of masochism and sadism in his work *Being and Nothingness* (1956). Here the Medusan imagery is elevated into a description of the human condition as consciousness seeks to objectify the other person and thereby escape from the petrifying glance of another consciousness. Simone de Beauvoir (1908–1986) built upon Sartre’s phenomenology of the gaze by formulating the topic in explicitly gendered terms, distinguishing between the aggressive masculine gaze and the defensive feminine look. Frantz Fanon explored similar phenomena by identifying the racialized perspective that projects the other as the object of racial oppression and prejudice (Fanon 1967).

Today the cultural construction of the gaze has led to a number of significant lines of research. Feminism’s critique of patriarchal modes of experience, including the phallocentric ways in which women’s bodies and female experience are cast into “objective” terms, is frequently formulated in “objective” terms, resulting in representations of women as an “object” of male desire. In a similar vein, John Berger has explored the male gaze and its role in creating representations of the female body in the history of Western art and, more particularly, in the history of the two- and three-dimensional nude figure (Berger 1972). Noteworthy in the field of media and film studies is Laura Mulvey’s psychoanalytically inspired work on the voyeuristic conventions of Hollywood cinema, and more especially her theory of the phallocentric links between male visual pleasure and narrative cinema (1989). Erving Goffman’s investigations of the “interactional work” of seeing and being seen—for example, the blank “stare-into-the-distance” assumed by urban passengers (the kind of neutral stare adopted in situations such as sharing an elevator, traveling on the subway, standing in line, etc.)—led him to his concept of “civil indifference.” Goffman’s research (1963, 1970) was prefigured by the German sociologist Georg Simmel (1858–1918), who is well known for pioneering work in the social phenomenology of the blasé attitude of cosmopolitan life. For Simmel, the urban metropolis creates forms of life where the self lives in a world of strangers, is continuously observed by the disinterested eyes of crowds, and loses the potential of creativity envisoned.

The look and its social analysis continues to play an important role within the field of visual culture theory and research. Popular culture is increasingly defined as a culture of global visibility, where all signifiers are either explicitly or implicitly reconfigured in voyeuristic terms—a multimedia world-industry of images designed to be looked at. Today computer-based communications, TV, film, and digitized multimedia provide the ultimate technological means that extend the social relationships embodied in gazing to a planetary stage. The related concepts of “the society of the spectacle,” “simulacral culture,” and the surveillance society have been developed to explore new geographies of power as these are redefined by the electronic media of watching, staring, and controlling the social field.
The state's structural characteristics of territoriality, sovereignty, and centralized government are exercised through the application of general laws that are considered authoritatively binding on the territory's inhabitants. These laws are always reinforced by a corresponding form of state consciousness or ideology of legitimation. The state always derives its legitimacy from an operative myth of the state's origin or foundation, such as a belief that the law is received by a state's priests or wise men directly from the gods, or that the state is founded by heroes with exceptional virtues, or that the state was established by contract among its citizens. Yet, as a matter of fact, all states arise from a system of class stratification, which is reproduced by the state as one of its main political and economic functions. Class, as Friedrich Engels (1972) argued, is not the only kind of social stratification that exists in state societies—it generally coexists with gender, racial, or ethnic forms of stratification—but class stratification is a unique attribute of state forms of governance.

ORIGINS AND FORMS OF THE STATE

Scholars have proposed many different typologies of state forms, but historically, as Nelson (2006) states, there are four fundamental forms of state: (1) ancient city-states, (2) ancient empire-states, (3) modern city-states, and (4) the modern nation-state. The origins of the state are generally traced to the late Neolithic period (3000–4000 BCE), or about 34,000 years after the first homo sapiens.

The first archaic states emerged on the banks of the Tigris and Euphrates Rivers (Mesopotamia), the Nile River Valley (Egypt), the Yellow River Valley (China), and the Indus River Valley (India).

Geography was a key factor in the origins of the state, because the fertility of these river valleys supported large settled agricultural populations, while the agricultural surpluses generated by these peoples made it possible to store and redistribute crops and to support the specialized craftsmen, warriors, priests, and administrators critical to state formation. Karl Wittfogel's (1957) hydraulic thesis of state formation notes that complex irrigation and flood control systems were necessary to realize these agricultural surpluses, while the construction and maintenance of these systems required increasingly centralized forms of political control. As Morton Fried (1967) and Jonathan Haas (1982) observe, this centralization of political authority and the emergence of social differentiation based on function mark the origins of the archaic state.

ANCIENT CITY-STATES

The first archaic states were created by the Sumerians of Mesopotamia about 3500 BCE, but within a few hundred years (3100–2320 BCE) many of these archaic states had...
evolved into fully developed city-states. The first real states were city-states, and the largest among them sometimes had tens of thousands of inhabitants. The ancient Sumerian city-states were typically warlike and in some cases expansionary. The fact that many ancient cities were defended by walls and fortifications suggests that the city-state, which quickly spread to other parts of Mesopotamia, did so partly as a result of the conquest of other peoples and partly as a way to defend against the threat of the Sumerian city-states. Significantly, these states not only centralized political authority within a defined territory, but eventually developed concepts of law that were first enunciated in the Hammurabic Code, a code of written law promulgated by Hammurabi, a king of Babylonia (1792–1750 BCE). Hammurabi’s Code influenced the emergence of legal systems in other Near Eastern states and was transmitted as a model to other empires in the Near East, Mediterranean, and later Europe.

The Egyptian state emerged almost simultaneously with the Sumerian city-states in 3100 BCE. In both regions, the sovereign authority of the state and its legitimizing religious myth were embodied in the person of a king, who claimed power either as a deity (Egypt) or as the voice of the gods (Sumeria). The centralized bureaucratic, military, economic, and ideological power of these kings far surpassed that of any previous tribal chieftain or clan elder. These kings commanded a formal state-military hierarchy, sat atop a rigid class system, and exercised preeminent religious influence within the state.

The Indus Valley Civilization emerged at about the same time (3300 BCE) on the Indian subcontinent, but this civilization did not achieve a state-level society until about 2600 BCE. Romila Thapar (2002) explains that, as in Sumeria and Egypt, the irrigation of the Indus River Valley generated large agricultural surpluses that supported burgeoning urban centers by 2500 BCE, and, over the next six hundred years, Indus Valley Civilization spread to the Ganges River basin and northern Afghanistan. However, it was not until 1000 BCE that the first recognizable city-states appeared on the Indian subcontinent, although by 500 BCE there were sixteen monarchies known as the Mahajanapadas covering the Indian subcontinent. These city-states, Vincent Smith (1981) notes, followed the earlier pattern of legitimizing the right of a king to his throne with genealogies devised by priests that ascribed divine origins to the rulers.

In their history of China, John Fairbank and Denis Twitchett (vol. 1, 1978) note that the Huang He Valley emerged as the first cultural center in China in the late Neolithic period (2100–1800 BCE); by the end of the second millennium BCE, the Zhou Dynasty (1027–771 BCE) was established in the Yellow River Valley and later in the Yangtze River Valley (770–221 BCE). The first Zhou king invoked “the Mandate of Heaven” to legitimize his rule, a concept that would influence almost every subsequent Chinese dynasty. During the Zhou Dynasty, the city-state spread throughout China until several hundred warring states were finally consolidated into seven states toward the end of the fifth century BCE.

ANCIENT EMPIRE-STATES

The ancient city-states were aggressive and expansionary regardless of where they originated, and their wars resulted directly in the formation of the first ancient empire-states. In most cases, Nelson (2006) observes, the basis of early state formation was the city, with empires arising as a secondary state formation from a city-state’s imperial expansion. The Assyrians built the first empire-state, starting with Sargon of Akkad, who became the first king to successfully assert political control over inhabitants living beyond his city-state (2371 BCE). Assyrian kings gradually asserted hegemony over all of Mesopotamia and the Fertile Crescent (2371–612 BCE), including Egypt for a short period (745–612 BCE). In building an empire of city-states, the Assyrians established the model for all subsequent ancient and classical empires, including the Persian, Macedonian, and Roman Empires, as well as many smaller empires, such as the Athenian, Phoenician, and Carthaginian Empires.

In India and the Far East, comparable configurations emerged from the warring city-states. During the time that large parts of India were subjected to the Persian and Macedonian Empires, the first Indian empire-state was the kingdom of Magadha, which emerged as a major power in northeastern India after subjugating two neighboring states (684–26 BCE). Numerous empires rose and fell in different parts of the Indian subcontinent, including the Satavahana Empire (230 BCE–199 CE) in southern and central India, and the Gupta Empire (240–550 CE), which united northern India. In 1526 Babur established the Mughal Empire, which was the first empire-state to unite most of the Indian subcontinent by 1600 CE. Its successor, the Maratha Empire, stretched across the entire subcontinent by 1760 but was eventually displaced by the British Empire (1757–1947 CE).

In China, the Qin Dynasty (221–207 BCE) was the first to subdue large parts of the core Han Chinese homeland and unite them under a centralized Legalist government. It also imposed a common system of writing and developed a state ideology based on Confucianism. China was an empire-state for most of its history, although historians generally divide its political development into early imperial (221 BCE–588 CE), classical imperial (580–1234 CE), and later imperial (1279–1911 CE) phases. However, as Peter Farb (1968) explains, there is
considerable debate as to whether the Meso-American empires, including those established by the Olmecs (1200–400 BCE), Mayans (250–900 CE), Incas (1197–1533 CE), and Aztecs (1248–1521 CE) should be considered ancient empire-states, archaic states, or a distinct tribal (i.e., non-state) form of tributary empire.

MODERN CITY-STATES
The ancient empire-states were often disorganized and short-lived in comparison to modern states. As S. N. Eisenstadt (1963) observes, it was not uncommon for empires to be conquered by rival empires, nor was it uncommon for empires to disintegrate back into warring city-states or into forms of feudalism because of weak political leadership, natural catastrophe, invasion, or rebellion. However, city-states and empire-states are the only known forms of state until the emergence of the modern state.

The basic structural characteristics of the modern state are identical to those of earlier state forms. However, most modern states tend to manifest these characteristics on a different territorial scale (the nation) and to vest sovereignty in an impersonal legal system. In the modern state, sovereignty is asserted to reside in the impersonal state form, and not in the ruler as conceived in the archaic and ancient states. Thus, in the modern state, there is a firm distinction between the state and its government (rulers), which is a distinctive ideological characteristic of the modern state compared to earlier forms of state. As Nelson (2006) notes, the modern state has also evolved in tandem with the capitalist form of economy and is therefore generally linked to the reproduction of specifically capitalist forms of class stratification.

The origins of the modern state are found in the medieval towns of Europe, which, as a general rule, stood outside the stateless feudal system of political relationships based on personal rule. The medieval towns developed their own governing system based on the idea that the town (i.e., the state) was an abstract entity (corporation or universitas) that was by right free from outside control. Joseph Strayer (1970) notes that these commercial centers evolved into independent states, most notably in Italy and Germany in the fourteenth and fifteenth centuries. The German city-states of the Hanseatic League, which emerged from the mid-fourteenth century onward, constituted a trading and military alliance of modern city-states but never became a true state in itself. Venice is the only modern city-state to build a commercial empire-state (800–1797 CE) by asserting control over other cities and islands in the Mediterranean and Aegean Seas. Despite being largely displaced by the nation-state, Singapore, Monaco, and Luxembourg survive today as successful and prosperous modern city-states.

THE MODERN NATION-STATE
The modern state became largely synonymous with the nation-state beginning in Europe in the early 1300s. In parts of the world, such as Europe in the medieval era, China, and Japan, there was sometimes a concept of “the nation” or “the people,” which was united by geography, language, literature, custom, and religion; but there were not actual states with territorial boundaries coinciding with this legitimating idea. Indeed, following the collapse of empires in Europe, China, Japan, and India, and their disintegration into feudalism, the state often ceased to exist as a form of political organization. Feudal forms of political organization were premised on structural characteristics that are the opposite of a state: (a) extreme decentralization and (b) the privatization of social, economic, and political power.

The modern nation-state originated in Europe as powerful monarchs in France, England, Russia, Spain, Sweden, and Denmark waged continuous wars to unify their “nations.” The political and religious wars that engulfed Europe for four centuries finally culminated in 1648 in the Peace of Westphalia, which codified the modern system of nation-states as international law by recognizing fixed national boundaries and the sovereignty of states within their territories. However, the system of European nation-states was not actually completed until the unification of Germany and of Italy in 1871.

It has been argued that, because most of the major and minor European nation-states were all colonial and imperial powers from the 1500s onward, the major nation-states have always been nation-state-empires. In fact the nation-state as codified in the Westphalian system was largely transferred to other regions of the world through European colonial and imperial expansion. Some of these postcolonial states, such as those in North America (1700s), Latin America (1800s), China (1911), India (1947), and Africa (1950s–1970s), were established by revolutions of national independence. Other states established in Africa and the Middle East were artificial “nations” created by the retreating colonial powers after World War I and World War II. For this reason, however, many of the postcolonial states lack the fundamental characteristics of either a nation or a state, such as a founding or heroic myth to legitimize the state. These “nations” often have a stronger history of internal tribal and religious conflict, while they sometimes lack a common language or religion except as a legacy of the colonizing state. The shared characteristics of nationhood are often most common among political and economic elites but are not shared evenly by inhabitants, who continue to speak local dialects, follow traditional religious practices, or retain political loyalties to local tribes and clans.
**STATE ENTERPRISE**

A state enterprise is a large, complex economic organization owned and operated by a government rather than by a private individual or organization. Though an economic entity, it is totally encapsulated by the polity, with no separation of state and market. And very importantly, it also may transfer goods and services among suborganizations without explicit pricing of those transactions.
The problem posed by state enterprise is determining a single decision rule governing the economic behavior of multiple suborganizations controlled by a single decision maker, a rule that will lead to the realization of maximum profit for the entire group. It has been proven in the socialist calculation debate that maximizing the excess of revenue over cost from operations is the most fundamental economic problem, whether the economy is centralized or decentralized, privately or publicly owned, and whether this excess is labeled surplus, surplus value, or profit.

Although this form of economic organization dates to ancient times, this article will (1) trace briefly the development of such enterprises, and (2) trace equally briefly the development of the economic theory underlying the management of such enterprises from the Industrial Revolution in Europe to the present. Although state enterprises have developed in former European colonies in Africa, America, and Asia since decolonization, these are derived largely from metropolitan examples.

THE ECONOMIC HISTORY OF STATE-OWNED ENTERPRISES IN EUROPE, 1600–2000

In the early seventeenth century, the Dutch, Portuguese, Spanish, English, and French developed large, state-chartered multinational trading companies that lasted until the late eighteenth century.

The best example of the potential of state enterprise in this period was in ancien régime France. Richelieu established the model for an autarchic mercantilist state with new industries, a network of canals, and international trading companies on the model of the Dutch East India Company. He formed four chartered companies for the purpose of colonization but was unable to effectuate the entire system. His successor, Mazarin, appointed as finance minister Colbert, who expanded the principle of government control of enterprises to a wider range of industries and activities, enacting a much greater part of the system. Colbert established ten more trading companies. He systematically established royal monopolies for the production of luxury goods and government regulation of all commerce and production. The heyday of this policy, called mercantilism by its critics and later by economic historians, was between 1613 and 1767. Colbert was so successful at it that it is sometimes known as Colbertism. To conceptualize this French mercantilist economy mathematically, Quesnay, a critic of the system, developed his Tableau Économique. In 1954 Joseph Schumpeter called this a planned economy.

The practice of state control of enterprises survived the French Revolution and continued through the nineteenth, twentieth, and early twenty-first centuries, the state assuming ownership of such enterprises as canals, toll roads, toll bridges, toll tunnels, railroads, energy and electric utility companies, and airlines. In the post–World War II era, the state controlled over 50 percent of new investment based upon its ownership of enterprises. To optimize the output of these enterprises, it instituted an indicative central economic plan. That is, although private investors and consumers were not obligated to follow the government’s economic plan because of the overwhelming government importance in the economy, there were strong incentives to do so.

Prussia under Bismarck in the nineteenth century showed the greatest reliance on state enterprise to finance the operation of the state. In one year in the 1870s, Prussia received 398 million francs from state enterprise, most from state railways but also from state-owned mines, factories, salt works, state forests, and state farms. The Bank of Prussia, state mint, toll roads, and toll canals also yielded substantial revenue to the state. This Bismarckian system of enterprise ownership was continued and extended by all subsequent German governments and included such important state enterprises as Lufthansa, Veba, Viag, Volkswagen, and Salzgitter. After World War II, the United States enforced a quasi-competitive economy on the West Germans under their control that did not require the dismantling of the state enterprises just named. In contrast, the Soviet Union forced a system of state enterprise upon East Germany, largely the former Prussia. In its centrally planned economy, state-owned enterprises produced about 97 percent of total net national income in 1985, this proportion continuing until about 1994.

The Marx-Kautsky concept that the economy was a single enterprise that should be controlled by the state was adopted by the Bolshevik Party in Russia and applied to the Soviet economy after 1917. Between 1917 and 1921, the Bolshevik government transferred 37,000 enterprises from private to state control in Russia, including all firms employing over ten workers. Among these enterprises were Aeroflot and those of the Oil Syndicate, Petroleum Syndicate, or Naphtha Syndicate, organized in 1918. In 1965, there were about 200,000 enterprises in operation in the USSR. In 1988, Aeroflot was split into smaller groups of enterprises. Azneft, Grozneft, and Embaneft, the state production trusts in the Oil Syndicate, were privatized after 1991.

The economic planning agency in the USSR, established in February 1921, was known as Gosplan, an advisory agency to the Council of Labor and Defense (STO). From 1925 until 1927, Gosplan was structured with two levels of central ministries above production enterprises. Cycles of decentralizing restructuring occurred, with peaks in 1957 under Khrushchev, in 1961–1965 under

ECONOMIC THEORY OF STATE ENTERPRISES

Economic theories associated with the historical development of state enterprises include those of Augustin Cournot, Jules Dupuit, Léon Walras, Maurice Allais, and Gérard Debreu in France; Vilfredo Pareto and Enrico Barone in Italy; Karl Marx and Karl Kautsky in Germany; Vladimir Groman, Vladimir Popov, Wassily Leontief, and Leonid Kantorovich in the USSR; Jan Tinbergen in the Netherlands; Ragnar Frisch in Norway; Oskar Lange and Leonid Hurwicz in Poland; and Donaldson Brown, Alfred Bradley, Paul Samuelson, and Kenneth Arrow in the United States. Of these theorists, eight have been awarded the Nobel Memorial Prize in Economic Science since its establishment in 1969.

Interestingly, given the lead taken by France in the practice of mercantilist policy, there were few French academic writings on the doctrine in the sixteenth, seventeenth, and eighteenth centuries. Cournot in his 1838 Recherches introduced marginal cost pricing in government enterprises (toll roads, toll canals, and railroads, which were completely state owned by the 1870s), defining the marginal revenue and marginal cost functions to be the derivatives of the total revenue and cost functions, and prescribing a most efficient price as that attained at the equality of these two derivatives.

Dupuit in 1844 extended Cournot’s marginal analysis from production to consumer utility. Using taxation as an example, he argued that total revenue from a new public utility (state enterprise) would be greatest where marginal revenue from a change in a price (toll) was zero. He distinguished between the utility to the nation as a whole (social or state utility), and the utility of a consumer of a service (private utility). Private utility varied with the consumer, and state utility could be maximized by price discrimination, charging different prices to consumers based on their individual utility functions.

Following Marx’s 1859 lead in theory and the policy of the First International, which he cites, Walras from 1874 to 1877 developed a static model of a pure exchange economy of many sectors arrayed as an m-by-n plane matrix of linear demand and supply equations. When solved as a simultaneous equation system, this model yielded the quantity of output of all sectors used as inputs to each other sector and the prices at which these transactions took place. To begin operating the model, one was required to guess at the initial quantity of commodities held by each participant in the economy, and the prices of those commodities. The model then proceeded to final equilibrium by successive approximation.

The first explicit theoretical extension of the Marxian and Walrasian models was undertaken by quasi-socialist engineers Pareto and Barone in the 1890s. Pareto approved of the theory of class struggle and historical materialism but questioned the labor theory of value. In his 1896–1897 Cours d’économie politique, Pareto argued, using Walras’s general equilibrium model, that as an equilibrium was simply the solution to a set of equations, this solution could be calculated by a socialist planner as well as worked out in practice through a market. In 1897, Pareto said he had been able “vigorously to prove that the coefficients of production are determined by the entrepreneurs in a regime of pure competition precisely in the same way as a socialist government would have to fix them if it wanted to realize a maximum of ophelimity” (Pareto 1897, pp. 485–502). In his 1906 Manuel d’économie politique, Pareto, analyzing only production in a collectivist economy, stated that “prices and net interest on capital disappear as actual entities… but they will remain as accounting entities; without them the ministry of production would proceed blindly and would not know how to plan production.” Therefore, “[t]he phenomena we have just studied suggest, in an abstract way and without taking into account the practical difficulties, is an important argument in favor of collectivist production.” In the 1909 French revised edition of this book by Bonnet, all four sets of Walrasian mathematical equations, including the consumption set, were presented explicitly, but only in a 113-page appendix. For consumer utility, however, he substituted an Edgeworth indifference curve for a Walrasian (cardinal) utility function. Mathematically, this substitution made no difference in the equilibrium equations. However, the ordinality of the utility or individual preference equations meant that no empirical (numerical) solution could be calculated representing his maximum of ophelimity. His focus thus shifted from the Walrasian problem of proving the existence of a solution to a set of equations to maximizing satisfaction, a preliminary statement of economic optimization, the linear programming problem. This optimum was defined as the state at which no one can be made better off without making someone else worse off. The solution assumed that all equations in the system were differentiable.

French economic planning after World War II was based on the theory Allais provided in 1943. He proved that a general equilibrium was Pareto optimal and that it could be attained by a centrally planned economy. If monopoly exists, however, these results are vitiated, for Walrasian general equilibrium assumes perfect competition in all markets. From 1937 to 1943, he was adminis-
tractor of Nantes state enterprises, in control of railroads for five of the eighty-nine French departments.

Debreu in 1951 published an article in which he stated: “In an economy provided with a central planning board incarnating a social welfare function there is only one consumption unit. The whole economic system can be divided into nations among which consumption units are distributed.” In 1959, objectively following Hegel and Arrow, Debreu published an axiomatic analysis of the development of a perfectly competitive economy. He utilized topology to extend the input-output analysis from the Euclidean plane to the solid, from two dimensions to a potentially infinite number of dimensions. Arrow and Debreu went on to show that a Pareto optimum could be calculated based on an analysis of ordinal preferences.

In 1908, Barone set up a general equilibrium model with four groups of linear equations similar to that of the Walras-Pareto model, and set up successive approximations as the solution process. The number of variables was found to be equal to the number of equations so that the system was formally (mathematically) solvable, that is, determinate. The market prices of the purely competitive system were found to be equivalent to the Pareto accounting exchange ratios among commodities in a collectivist system established solely by the Ministry of Production.

Unlike Walras and Pareto, Barone in his mathematical model focused solely on the production sector. His equations represented empirically observable magnitudes—quantities, costs, and exchange ratios (accounting prices) among the n kinds of capital (enterprises) in this sector. Cournot marginal cost equality in all two-by-two-enterprise transactions was required for equilibrium. This represented Walrasian classical economics and Austrian capital theory.

Marx and Engels in 1848 called for the centralization in the hands of the state of the means of production, credit, transportation, and communication. In 1859, Marx referred to Petty's 1699 statement that the entire country is “one large scale industrial establishment.” Marx here stated, “The exchange-value of this particular commodity can therefore be exhaustively expressed only by the infinite number of equations in which the use-values of all other commodities form its equivalent.” In 1863 and 1885 the first and second volumes of Das Kapital appeared, in the second of which Marx stated, “from the standpoint of society as a whole, the aggregate capital appears as the capital of a single joint-stock company.” This was all a neomercantilist analysis, a systematic updating of Colbertism in mathematical terms.

Kautsky, the leading socialist theoretician after Engels's 1895 death, argued in the 1891 Erfurt Program, “The whole machinery of production will be turned into a gigantic concern subject to a single master [the state].” In a 1902 speech, he added that this required “systematic direction of production from a single point.”

The earliest attempt to construct an empirical table of the Quesnay sort, as suggested by Marx, was by the Menshevik V. G. Groman in 1923. STO ordered the Central Statistical Administration to construct a “balance of the national economy” for 1923–1924. Preliminary results were released in 1925. In 1926–1928, Pavel I. Popov, assisted by Lev N. Litoshenko and M. Barenholz, developed a rudimentary input-output model based upon Quesnay’s Tableau and Marx’s two-sector model of expanded reproduction. It attempted to build an “interbranch balance of productive links.” In 1935 Leontief began research that led to the development of the input-output table and an economic theory underlying it. He recast the Walras model into an “input-output” form that facilitated actual calculation. Defining industries and sectors in terms of available statistical data series, he then constructed such a table to estimate coefficients of the U.S. economy in 1941 and 1953. In 1949, he constructed a 500-sector model of the U.S. economy, each sector modeled as a linear equation.

Kantorovich in 1939 showed that problems of economic allocation of resources can be reduced to maximizing a function subject to constraints, a linear programming approach to determining the optimum price in enterprises, a procedure foreshadowed by Pareto. He also introduced the distinction between the primal and dual in linear programming. He developed the “method of decisive multipliers,” which were interpreted as “shadow prices.” With regard to the necessary use of prices to achieve an optimum under socialism, he was objectively a follower of Lange, and through him of Pareto and Barone.

Tinbergen in 1936 constructed a twenty-four- or twenty-seven-equation input-output (econometric) model of the Dutch economy and in 1939 developed a thirty-eight-equation model of the U.S. economy for the League of Nations. These models used prices imposed by the central planner to imitate the operation of the purely competitive market, thus creating what came to be called market socialism. After World War II, he served for a decade as head of the central planning bureau of the Netherlands.

Frisch constructed theories of a price-driven socialist plan, a form of market socialism, but never actually held an official position in the planning office. To solve the input-output matrix, he developed in the early 1930s aspects of the technique later called linear programming.

In 1936 and 1937, Lange set out a socialist economy in which there were markets for consumer goods and labor services but not for capital goods. Prices for capital and nonlabor goods were not market prices but "mere
indices of alternatives available, fixed for accounting purposes.” He thus adopted the Pareto-Barone focus on accounting prices. For equilibrium, both market prices and accounting prices were determined by the condition that the quantity of each commodity demanded is equal to the quantity supplied. Each plant must produce the quantity of output that minimizes average cost, and each industry must produce the quantity that can be sold to consumers at that minimum average cost of production. These two rules make prices given by the Central Planning Board appear to consumers precisely as prices given by a perfectly competitive market. The solution to the allocation problem begins with random (guessed) prices chosen by the Central Planning Board and proceeds by iteration to a final solution. In a centrally planned economy without any markets, prices would be determined in precisely the same way. The socialist planning method, in either the decentralized or centralized form, would reach an equilibrium faster than a perfectly competitive market because the Planning Board would have more information about the network of prices and quantities than any individual enterprise could possibly have.

In the 1920s, Donaldson Brown and Alfred Bradley, economists at General Motors Corporation (GMC), took on the task of developing a price policy for the recently divisionalized firm, and following the lines of Pareto and Barone, they visualized GMC as a socialist economy of the Marx, Kautsky, and Soviet kind. Each division was viewed as an independent enterprise. All transfers between divisions within the firm were therefore priced, as previously all transactions between GMC and outside firms had been priced. This allowed GMC to allocate resources within the firm more precisely and hence to function more efficiently. The Brown-Bradley program corrobated from the capitalist side the theory being developed nearly simultaneously in the Soviet Union. Clearly implicit in all these findings was that the method of optimizing returns was the same for a privately owned enterprise as it was for a collectively owned (state-owned) one. Optimization required a “visible hand,” that is, management of the enterprise, or economic planning.

Samuelson in 1941 and 1947 defined economic equilibrium to be a mathematical optimization problem, following Pareto. He introduced from physics the use of Langrangian multipliers in solving constrained optimization problems, defining these as either prices or costs. He explicitly equated this price to conceptions of Pareto, Barone, Hotelling, and Lange in the socialist planning debate. He attributed the compensation principle to Barone and not as have others to Kaldor and Hicks. He adopted Pareto’s differentiability assumption and showed that the operation of the model was equivalent to solving a system of differential equations.

Arrow in 1951 amalgamated many individual preferences into one social preference, setting the problem as one of choosing alternative “social states,” that is, income and wealth distributions, and concluding that the rational decision criterion is Pareto optimality. In 1959 Arrow introduced the concept that for exchanges between the divisions of a capitalist firm, “the same price should be charged as if it were a transaction with another firm.” Adopting von Neumann’s proof that the Lagrange multiplier was equivalent to the shadow price, he argued that only a process of successive approximations could determine the shadow price. He also redefined the concept of profit maximization as maximization of “the sum of the discounted profits” of the firm over time. This made profit maximization a dynamic rather than a static process. In 1969, he returned to the application to enterprises, stating, “An incentive for vertical integration is the replacement of buying and selling on the market by the cost of intrafirm transfers; the existence of vertical integration may suggest that the costs of operating competitive markets are not zero, as is usually assumed in our theoretical literature.”

The chief mathematical tool used by all those writing from 1838 to 1956 was calculus and matrix algebra. Samuelson in the 1940s, and Arrow, Debreu, Hurwicz, and Hirschleifer in the 1950s, experimented with more powerful methods of analysis, including dynamical systems and topology. The last four showed that it is possible to reach a solution to the general equilibrium model without the assumption of universal differentiability.

State of Nature

**Julian Ellison**

STATE OF NATURE

State of nature refers to a condition in which there is no established political authority. It is essentially a state of complete freedom. Political theorists have used it to better understand human nature and, typically, to justify the rationality of a particular type of government. Proponents claim that the state of nature provides insight into the inherent dispositions and inclinations of human beings. Because individual conduct is not coerced by political authority, it will reflect how humans behave naturally.

Social contract theorists commonly speculate about what life would be like in the state of nature. Based on their understandings of human nature, they argue that individuals in the state of nature face certain threats to their well-being. Consequently, rational people should consent to recognize the authority of a state in exchange for protection from these threats. The extent of the state's authority and the safeguards it is responsible for providing are functions of the theorist's view of human nature. Generally, an optimistic view of human nature leads to the advocacy of a state with limited powers, while a more pessimistic view is associated with a more powerful state.

Thomas Hobbes (1588–1679), in Leviathan (1651), first used the state of nature to justify the authority of the state. He claims that the state of nature would be a war of “every man against every man” (p. 76). Hobbes's characterization of the state of nature results from his view of human nature (see chapter 13). He believed that all people are basically equal physically and mentally, so no individual is safe from the machinations of others. Moreover, humans are innately competitive, diffident, and glory seeking. Therefore, they are prone to attack others for gain, preemptive self-defense, and recognition. Given this view of human nature, he envisioned the state of nature as a place in which violence would always be a threat, that is, a state of “war.” There would be no industry, culture, knowledge, or society and “worst of all, continual fear, and danger of violent death” (p. 76). Hobbes famously concludes that, in the state of nature, “the life of man” is “solitary, poor, nasty, brutish, and short” (p. 76).

The solution to this state of war, according to Hobbes, is the creation of an overarching government, that is, a leviathan. Because human nature disposes people to conflict and violence, only an all-powerful state can maintain order. Consequently, people should give up almost all personal autonomy, retaining only their right to self-defense. Hobbes contends that an authoritarian government is not only necessary but preferable to a state of nature.

John Locke (1632–1704), in Two Treatises of Government (1690), also uses the state of nature in his justification of limited government. He claims that the state of nature would be characterized by “inconveniences” (p. 276). Human beings, according to Locke, are rational creatures able to understand the law of nature using reflective reason (see chapter 2, Second Treatise). This law requires that people not harm another individual’s natural right to “Life, Health, Liberty, or Possessions” (p. 271). It also obligates them to help preserve the lives of others when possible. Finally, it gives people the right to enforce the law and punish transgressions only so far as to deter future crime. Locke believes that humans in the state of nature are typically inclined to respecting the natural right of others. The problem is that people are unable to be objective when their own interests are at stake. Humans
are naturally disposed to overpunishing transgressions against themselves, family members, or friends. Retaliation inevitably creates an escalating cycle of violence.

Government, according to Locke, can provide a remedy, restraining “the partiality and violence of Men” (pp. 275–276). By objectively adjudicating violations of natural law, it can prevent the cycle of violence resulting from subjective enforcement. Rational people should be willing to give up their natural right to enforce the law of nature to the state. In exchange, the state becomes responsible for enforcing their natural rights to life, liberty, and property. Because the state of nature is merely a state of inconvenience, it does not warrant the establishment of a more intrusive and powerful government.

Jean-Jacques Rousseau (1712–1778), in the Second Discourse on the Origin of Inequality (1754), provides a much more brutish understanding of the human condition in the state of nature. He claims that previous theorists mischaracterized the state of nature because they had mistaken socialized inclinations for natural attributes. “They spoke about savage man, and it was civil man they depicted” (p. 38). Rousseau claimed that humans in the state of nature have only three basic physical desires: food, sex, and sleep. Their only fears are hunger and pain. No significant human conflict arises in the state of nature because people have very limited desires and an inborn sentiment of pity, which inspires a form of natural goodness. All other human passions and desires, along with such qualities as rationality and virtue, are acquired in society. Human beings in the state of nature, therefore, are simply animals, albeit with unrealized civilizing potential. They are in essence noble “savages.”

The state of nature is a thoroughly modern approach to studying human nature and justifying the responsibilities of the state. It embodies three basic principles of liberal political theory: the priority of the individual, equality, and personal freedom. First, the state of nature’s asocial condition suggests that humans should ultimately be understood as abstract individuals. Second, humans in the state of nature are considered morally equal, with no person having the authority to dominate anyone else. Third, people are portrayed as autonomous, self-determining creatures, thus emphasizing freedom as a natural human quality. This depiction of the human condition is quite contrary to the classical view, which assumes that human beings cannot be understood outside of the society in which they live.

The state of nature was a particularly popular thought experiment during the seventeenth and eighteenth centuries before falling out of vogue. Nonetheless, it continues to influence contemporary academic and public discourse. For example, the “original position” in John Rawls’s Theory of Justice (1971) is a conceptual variation of the state of nature. In international relations, some scholars use the idea of a state of nature to theorize about the relationships and interactions between political states. The imagery produced by state-of-nature theories also maintains a grip on the popular imagination, from Hobbes’s nightmarish war of all against all to Rousseau’s romanticized noble savage. Locke’s natural rights in the state of nature have also been passed down through the American Declaration of Independence as unalienable rights to “life, liberty, and the pursuit of happiness.”

STATE-DEPENDENT RETRIEVAL
State-dependent retrieval describes the experimental finding that subjects who learn something in one state (e.g., a drug, nondrug, or mood state) remember more if they recall in the same state, rather than in a changed state. Context-dependent retrieval describes the same phenomenon. Numerous states or contexts can act as retrieval cues to facilitate remembering if reinstated at recall. Graham Davies and Donald Thomson (1988) provide an excellent reference source describing the different contexts found to influence memory. These include external states, where the learning environment is reinstated (e.g., the room, or a crime scene), and internal states, where the inner experiential state is reinstated (e.g., with alcohol, drugs, or mood states). In one experiment with subaqua divers, the divers who learned and recalled word lists in the same context (on land or under water) remembered 50 percent more words. In another experiment, subjects performed memory tasks while sober or under the influence of alcohol. Twenty-four hours later they were tested under the same or different conditions; those who learned and recalled in the same state remembered more than those...
Statelessness

who changed states. Endel Tulving and Donald Thomson proposed that specific retrieval cues facilitate recall if the information about them is encoded and stored at the same time as the material to be remembered (Tulving and Thomson 1973). Their “Encoding Specificity” principle states that a cue must reinstate information present in the original memory trace to be effective at retrieval.

State-dependent retrieval has been studied extensively in animals using drugs to induce state changes. Donald Overton (1974) commented that many experiments using pharmacologically induced states suffer from methodological problems. Eric Eich (1980) reviewed fifty-seven experiments of human drug state-dependent retrieval and noted that the phenomenon is not always reproducible; it is also unclear whether drugs exert an influence directly on memory or indirectly through changes in mood.

Researchers became interested in the effects of mood on memory, particularly the perpetuation of depressive mood states. Mood was thought to have a state-dependent effect on memory. This suggestion arose from the findings of studies in the 1980s by John Teasdale (1983) and others that happy past memories were significantly more likely to be retrieved in happy moods and sad memories more often in depressed moods. These mood congruity effects were thought to result from mood state acting as a context; support for the mood-state-dependent retrieval explanation came from experiments demonstrating that similarity of mood state at time of encoding and retrieval produced less forgetting of emotionally neutral material than changed mood states. Gordon Bower (1981) advanced his “Associative Network Theory of Memory and Emotion” to explain these findings, but controversy surrounded mood-state-dependent retrieval; the effect was elusive and unpredictable (Blaney 1986; Kuiken 1991). Analysis of experiments investigating mood-state-dependent retrieval identified methodological problems that contributed to the controversy surrounding the reliability of the effect (Kenealy 1997). In particular, designs confounded encoding and retrieval by not measuring (or reporting) initial learning scores; some lacked objective measures of mood manipulation; and others used the same method of mood induction at encoding and retrieval, confounding the effects of mood and induction procedure. The phenomenon is intriguing, but the evidence does not allow definitive statements to be made concerning the generality and reliability of state-dependent retrieval.

STATELESSNESS

A state, or more broadly in the Anglo-Saxon tradition, a nation-state, comprises a population living on a delineated territory with internationally respected boundaries and under a state apparatus whose prime and most distinguishing characteristic is the monopoly of violence. This definition follows that of Max Weber, whose original 1922 formulation of the monopoly of Gewaltsamkeit (physical violence) implies a potential use of that violence. At best a state carries international and internal legitimacy and thus is widely respected.

Stateless people are without legally enforceable claims to any internationally recognized state. The “host states” usually withhold the supply of public goods like security, law and defense from stateless people, at least to some extent. People can be or become stateless, i.e., are not recognized as belonging to a specific territory that meets the initially stated requirements. Stateless persons may be registered as nonnational residents, foreigners or categorized as nationals of another state even when that state does not accept them as nationals and thus will not protect them.
On the other hand, they might have advantages in avoiding taxes and the military draft.

The United Nations, early in 2006, reported 2,381,900 stateless people around the world, which was more than a 50 percent increase over 2005. The United Nations High Commissioner for Refugees (UNHCR) notes that precise numbers are difficult to ascertain, and that the actual number may be much higher, of even more than 11 million stateless people.

Four broad categories emerge: first, people that never were taken care of in their own state or that never have raised such claims. These are mostly members of small ethnic tribes living at a subsistence level, such as natives of the Amazonas region or the Pygmies of Africa. Frequently, these people were driven into their current settlement areas by more powerful contenders (e.g., Brazilian settlers or colonists in South Africa). In cases like the Aborigines of Australia and the Maoris of New Zealand, the new conquering state eventually granted them passports.

Second, people lose their attachment to their state for temporary reasons such as external conquest or internal strife, epidemic diseases or natural catastrophes. They may still have their personal documents but their state territory may not be accessible for them due to the given reasons. Losing personal documents in these situations makes claims for return even more difficult.

Third, a state may have ceased to exist due to external subjugation or exhaustion of the soil. This either forces the indigenous population to become (second-class or slave) citizens of the new state as, e.g., under Mongolian rule, leads to their annihilation in that territory, as with most of the Jews after Titus' victory in the first Jewish-Roman War (66–73 CE), or forces them abroad. If the new state will be widely recognized internationally, the third category of stateless people merges to refugees who carry no longer internationally recognized documents.

In cases of state collapse (Rotberg 2004) citizens may still carry a passport but have no state authority to protect them. A partial recovery of a state as in Lebanon or sort of a foreign protectorate is one of the possible outcomes here, as in Somalia on the part of the Ethiopian government in 2007, as is the permanent intermingling of internal and external ethnic divisions (Carment and James 2004).

There is a fourth category of people who cannot guarantee their economic survival in their home state, throw away all their documents (Sans-Papière) to avoid sanctioning on the part of the recipient states, and try to enter another state illegally as a refugee. From these four basic categories many more combinations can be derived, in particular with respect to forms of diaspora (Shain and Sherman 1998).

The lower the level of development in the lost or given up territory, the fewer and less recognized the documents and skills of these refugees, the harder the economic consequences for them in having to accept Lumpenproletariat jobs in their new states. Their status of illegal (and often unwanted) immigrants is permanently insecure. The numbers of these immigrants swell (now a sizable nine-digit figure), the larger the persistence of the North-South divide (Mediterranean connex, influx from Mexico, and mutatis mutandis of the Chinese in Eastern Russia). In general, the somatic and psychic illnesses are severe among these exile-driven people, even though a sizeable portion of this group is composed of rather robust and resilient young men. Their success for integration into a new culture depends on family networks and middlemen-minorities helping out with jobs and shelters, and, last but not least, on the pull-effects a generous and highly-developed welfare-state exerts on citizens of underdeveloped economies.

There can be vast overlap between these four categories of stateless people. The first dividing line is whether these individuals possess a valid passport. Otherwise the likelihood diminishes rapidly that any state will claim these people. There is also a small numbers effect here making for more benevolent reactions on the part of recipient states. Sometimes, e.g., with the Vietnamese boat-people or the Algerian Harkis, this is an offspring of joint fighting in an external war. Thus, there is a two-dimensional space formed by the dimension of passport-ownership (yes, restricted in various degrees, no) and the dimension of a claiming/recipient state (yes, with restrictions, no). The matter becomes more complicated when some family or clan members of an ethnic group that does not have its own state, like the Roma or the Kurds, live with their passport-owning brethren. A continuum of severity, or in a different terminology: a property space of legality and legitimacy, stretches from (1) no passport and no-state-claim people (like the Bushmen) via (2) (restricted) passport-ownership and no state claim (German Jews driven into exile under Nazi rule), (3) the lack of a passport, but a claiming state (e.g., tourists abroad in a catastrophe like the tsunami of 2004) to the (4) full protection of a passport and a claiming state.

In any case, a claiming state is more important for ultimate safety than possession of a formal passport. In that respect, emphasis has been duly laid on a functioning state apparatus as a variable in its own (Linz and Stepan 1996).

As to Kurdish and Palestinian refugees, it is not only their stronger “host” states that do not concede a joint state for the across-border population. The major powers of the world in this power rivalry, above all the United States...
States, turn down claims for an independent state on the historically claimed territory.

Under conditions of globalization with workers and tourists seeing the world, the need for shelter in a home state with its guaranteed jurisdiction becomes even more important, paradoxically the more often the boundary of one’s own state is crossed. The risks intensify for children born and raised in a third country that has not issued a passport to either parent.

**STATIONARY PROCESS**

A *time series* is a set of data ordered in time, usually recorded at regular time intervals. In probability theory, a time series \( \{x_t\} \) is a collection of random variables indexed by time. In the social sciences, examples of time series include the quarterly level of the gross domestic product, the monthly inflation rate, the annual level of crime, and the annual population growth. One of the main features of time series is the interdependency of observations over time. This interdependency needs to be accounted for in the modeling of time series data, in order to improve understanding of their temporal behavior and forecasting of their future movements.

The class of all models for time dependent data is far too large to enable methods of analysis to be designed that would be suitable for all these models. The modeling of the interdependence becomes an impossible task, and a certain degree of stability or invariance in the statistical properties of the time series becomes essential for its modeling.

*Stationarity* broadly refers to some form of statistical stability or equilibrium. Stationarity is a key concept in the analysis of time series data, as it allows powerful techniques for modeling and forecasting to be developed. There are different forms of stationarity, depending on which of the statistical properties of the time series are restricted. The two most widely used forms of stationarity are: weak stationarity and strict stationarity.

**WEAK AND STRICT STATIONARITY**

A time series \( \{x_t\} \) is said to be **strictly stationary** when the probability density function of the collection of the random variables \( x_{t_1}, \ldots, x_t \) is the same as that of the random variables \( x_{1-h}, \ldots, x_{t-k} \) for all integers \( t_1, \ldots, t \) and positive integers \( k \) and \( h \). The strict stationarity property restricts the probabilistic properties of any collection of random variables to be invariant to time shifts, which implies that the probabilistic behavior of each random variable is the same across time.

A time series \( \{x_t\} \) is said to be **weakly stationary**, sometimes referred to as second-order or covariance stationary, when

\[
E(x_t) = \mu < \infty, \text{ for all integers } t,
\]

\[
\text{Var}(x_t) = \sigma^2 < \infty, \text{ for all integers } t,
\]

\[
\text{Cov}(x_t, x_{t+h}) = \gamma(h), \text{ for all integers } t \text{ and } h.
\]

The weak stationarity property restricts the mean and variance of the time series to be finite and invariant in time and takes the linear dependence between two distinct observations (as measured by the covariance) to be a function of the time distance between them. The function \( \gamma(h) \), for integers \( h \), is called the autocovariance function. The function \( \rho(h) = \gamma(h)/\sigma_2 \), for integers \( h \), is the autocorrelation function.

Strict stationarity implies weak stationarity when the mean and variance of the time series exist. The two forms of stationarity are equivalent if the time series follows the *normal distribution*. Overall, weak stationarity is less restrictive than strict stationarity. Moreover, it turns out that the weak stationarity condition is sufficient for most of the statistical results derived for cross-sectional data to hold. For these reasons, weak stationarity is employed more often than strict stationarity. Various authors use the term *stationarity* to refer to weak stationarity. Figure 1 shows one hundred simulated data from a weakly stationary time series.

A simple example of a weakly stationary time series is the *white noise sequence*, a sequence of *zero mean*, con-
stant variance, and uncorrelated random variables. Probably the most well-known model for weakly stationary time series is the autoregressive moving average of orders $p$ and $q$, or ARMA($p,q$), model with appropriate restrictions on its coefficients, where the variable under consideration is written as a linear combination of its own $p$ past values, an error term (usually taken to be a white noise sequence), and $q$ past values of the error term. The ARMA($p,q$) model was popularized by George Box and Gwilym Jenkins (1970).

Stationarity plays an important role in the forecasting of time series data. Suppose that at time $t$ we are given a set of data $x_{t-n}, \ldots, x_t$ and we wish to forecast the future value $x_{t+h}$. In predicting the value $x_{t+h}$ we would make use of the given data, and we would predict the value $x_{t+h}$ by some function $f$ of the given data. To determine which function $f$ gives the best forecast, a measure of accuracy or loss function is needed to evaluate how accurate a forecast is. The most commonly used measure in prediction theory is based on the mean squared error (MSE) of the forecast, and the function $f$ is chosen so that the MSE is minimized. It turns out that the function $f$ that produces the smallest MSE is the conditional mean of $x_{t+h}$ given the available information $x_{t-n}, \ldots, x_t$.

$$\hat{x}_{t+h} = a_0 x_t + a_1 x_{t-1} + \ldots + a_n x_{t-n},$$

where $a_0, a_1, \ldots, a_n$ are parameters that need to be estimated. The assumption of weak stationarity of the time series $\{x_t\}$ guarantees that the parameters $a_0, a_1, \ldots, a_n$ are invariant in time and therefore can be easily estimated from the data.

A detailed discussion of the properties, modeling, and forecasting of stationary time series can be found in Peter Brockwell and Richard Davis (2002).

**NONSTATIONARITY**

The conditions for stationarity, weak or strong, can be violated in many different ways. Time series that do not have the stationarity property are called nonstationary. Examples of nonstationary time series data include the

**Figure 1**

Simulated time series data from a weakly stationary model.
levels of the gross domestic product and population, which do not fluctuate around a constant level, but show overall an upward time trend. For these series, the average behavior for the beginning and the end of the sample differs, which rules out the possibility that the time series is stationary. A trend component in the data is one of the most common cases of nonstationarity in economic time series. Popular models for capturing trend behavior are the linear trend and random walk models.

The linear trend model assumes that the random variable $x_t$ of the time series can be written as the sum of a deterministic linear trend $\alpha + \beta t$ and a white noise random variable $\varepsilon_t$,

$$x_t = \alpha + \beta t + \varepsilon_t, \quad (1)$$

where $\alpha$ and $\beta$ are constant parameters. Under the linear trend model (1), $x_t$ is regarded as being scattered randomly around the trend line $\alpha + \beta t$, with the fluctuations around the trend line having no obvious tendency to increase or decrease. It follows that the mean of $x_t$ depends on time $t$, $E(x_t) = \alpha + \beta t$, so that the time series $\{x_t\}$ is nonstationary. Deterministic nonlinear functions of time $t$ could also be considered to describe the trend of $\{x_t\}$.

The random walk model assumes that the random variable $x_t$ of the time series can be written as the sum of its previous value $x_{t-1}$ and a white noise random variable $\varepsilon_t$,

$$x_t = x_{t-1} + \varepsilon_t, \quad (2)$$

Under the random walk model (2), from one period to the next, the current observation of the time series takes a random step away from its last recorded value. The random walk model (2) can be extended to include an additive constant $\delta$, and becomes the random walk with drift $\delta$ model,

$$x_t = \delta + x_{t-1} + \varepsilon_t, \quad (3)$$

If it is assumed that the time series $\{x_t\}$ starts from some initial value $x_0$, then it can be shown for the random walk with drift model (3) that the mean and variance of $x_t$ depend on time $t$, $E(x_t) = x_0 + \delta t$ and $\text{Var}(x_t) = t\text{Var}(\varepsilon_t)$. Therefore, a time series $\{x_t\}$ following the random walk without or with drift models (2) and (3) is nonstationary.

The trend component in the linear trend model (1) falls in the category of deterministic trends, as it is assumed that the trend of the time series is a deterministic function.

Simulated time series data from the linear trend model (solid line) and the random walk with drift model (dotted line)

Figure 2
of time. On the other hand, the trend component in the random walk without or with drift models (2) and (3) belongs in the category of stochastic trends, since for these models the trend of the time series is taken to be driven by the lagged time series, which is stochastic.

The difference between deterministic and stochastic trends can be seen from the models (1) and (3). The mean of \( x_t \) is a linear function of time \( t \) for both the linear trend and random walk with drift models (1) and (3), but the variance of \( x_t \) is increasing in time \( t \) for the random walk with drift model (3), and is constant in time \( t \) for the linear trend model (1). Another difference between the two models is the nature of the effect of shocks to future values of the time series. For the random walk with drift model (3) the effect of a shock is permanent, while for the linear trend model (1) it wears off. Figure 2 shows five hundred simulated data from the linear trend and random walk with drift models (1) and (3) with parameters \( \alpha = x_0 = 0 \) and \( \beta = \delta = 1 \).

A detailed discussion on nonstationary time series and the various models for the trend can be found in James D. Hamilton (1994).

**TRANSFORMING NONSTATIONARITY TO STATIONARITY**

The analysis of nonstationary time series is more complicated than that of weakly stationary ones. Moreover, statistical inference that involves nonstationary data is usually nonstandard, in contrast to weakly stationary ones. For these reasons, if nonstationarity is evident in the data, it is common practice to apply some transformation to the data that makes them weakly stationary and then apply statistical analysis on the transformed data.

For example, if a time series \( \{x_t\} \) follows the linear trend model (1), then if one subtracts the trend \( \alpha + \beta t \) from \( x_t \), the transformed series is a white noise sequence, which is weakly stationary. Nonstationary time series that become weakly stationary after extraction of a deterministic trend are described as trend-stationary.

Another important transformation that can make nonstationary data into weakly stationary is the difference operator. The difference operator, denoted usually by \( \Delta \), is such that when applied to \( x_t \) the result is \( x_t - x_{t-1} \).

If it is assumed that the time series \( \{x_t\} \) follows the random walk without or with drift models (2) and (3), then the difference operator transforms the data into a white noise sequence without or with an additive constant (the drift), which is weakly stationary. In some cases, it could be required that the difference operator is applied more than once to the data to achieve weak stationarity. Nonstationary time series that become weakly stationary after applying the difference operator are referred to as difference-stationary.

Difference-stationary time series are often described as being integrated of order \( d \), denoted as \( I(d) \). The parameter \( d \) is the order of integration and is the number of times that the difference operator has to be applied to the data in order to achieve weak stationarity. In the case that we take \( d \) differences and the resulting time series follows a weakly stationary ARMA\((p,q)\) model, then the original time series follows the autoregressive integrated moving average of orders \( p, d, \) and \( q \), or ARIMA\((p,d,q)\), model of Box and Jenkins (1970).

For nonstationary economic time series, it is common that the order of integration is \( d = 1 \), and in a few cases is \( d = 2 \). Time series that are integrated of order 1 are referred to as having a unit root. Examples include the random walk with or without drift and the ARIMA\((p,d,q)\) with \( d = 1 \) models. Time series having a unit root have attracted particular attention in the literature of theoretical and applied econometrics.

More information on the topic of unit root time series can be found in William Greene (2003), including testing procedures to discriminate between weakly stationary and unit root time series.

**STATIONARY STATE**

Classical political economy, from William Petty, the Physiocrats, Adam Smith, and David Ricardo, to John Stuart Mill and Karl Marx, analyzed the dynamics of capitalist economies and investigated the sources of economic growth and development. In this analysis, a progressive or advancing state is one in which capital accumulation is proceeding, whether smoothly or erratically—in other
words, it is a condition of positive economic growth, usually associated with high and rising profits and wages. An economic system experiencing negative growth is said to be in a declining state. Thomas Malthus and Ricardo focused much attention on various scenarios associated with decline—leading Thomas Carlyle to dub political economy “the dismal science”—while Marx made prognostications about its inevitability. A stationary state is one in which growth is neither positive nor negative. Until John Stuart Mill, the stationary state was, like the declining state, considered unwelcome, and growth was thought to benefit all three great classes of society: capitalists, landlords, and workers.

In his *Principles of Political Economy* (1848), Mill for the first time raised the possibility that the stationary state could be desirable (and economic growth undesirable). In addition, whereas in all the earlier classical authors the system’s movements were seen as governed by internal “laws of motion” that, while they could be identified and interpreted, could not be altered, in Mill, for the first time, the possibility that human intervention into the system could affect its outcomes was contemplated. Marx, of course, also put forward the idea that people make their own history (though “not exactly as they please”), but for Marx capitalism must grow (“Accumulate or die!”), and his analysis also viewed capitalism as incapable of being reformed, so change meant a transition to socialism. Strictly speaking, outcomes could be influenced by human interference even in Ricardo, where, for example, repeal of the corn laws could allow cheaper corn to be imported, supporting profits that otherwise were being squeezed by the artificially high price of corn—but this is a case of affecting the laws themselves, but of clearing the way for the “laws of motion” to operate to their fullest.

In *Principles*, Mill begins by affirming that the laws of production are, like the laws of physics, unalterable (although some might be guided within strict limits), but then suggests that the laws of distribution are capable of being guided by human institutions. For Mill, distribution is governed by the laws and customs of society. The nature of distribution varies from society to society and is subject to historical change. Like his predecessors in Classical political economy, Mill saw a tendency toward a falling rate of profit that would lead to a stationary state. However, whereas the earlier writers associated the stationary state with gloom and poverty, Mill saw it as the blissful final result of economic progress. Mill also considered the idea that a society could choose to adopt a stationary state, rather than wait for a stationary state to be imposed on it.

In the ideal stationary state, society would have achieved a sufficiently high level of wealth accumulation. Workers would be educated to realize the negative effects of population growth, and they would control their numbers voluntarily. As population growth reached a stationary stage, there would be no tendency for wages to fall and no reason for further growth in production. Mill was sure to note that a “stationary condition of capital and population implies no stationary state of human improvement” (Mill [1848] 1987, p. 751), thus making the distinction between quantitative growth and qualitative development. He also pointed out that his analysis applied only to the presently industrialized nations, and that what would later be called “developing” countries have not yet reached the level of economic well-being necessary to turn to zero growth.

Recently, ecologically oriented economists have cited Mill and put forward their vision of a steady-state economy, which is more or less the same idea conceived by Mill (see, for example, Daly’s notion of “an economy with constant stocks of people and artifacts” [1978, p. 17]). This is somewhat confusing, because in traditional growth theory the term steady-state refers not to zero growth, but to proportional growth. Frank Knight (1921) noted, for example, that John Bates Clark’s “static state,” which is an abstraction for methodological purposes, is not the same as the classical authors’ stationary state. Ludwig von Mises also expressed the sentiment that “[t]he idea of a stationary state is an aid to theoretical speculation. In the world of reality there is no stationary state, for the conditions under which economic activity takes place are subject to perpetual alterations which it is beyond human capacity to limit” ([1922] 1951, p. 196). In neoclassical economics, the term steady-state is used to indicate not a state of zero growth, but rather a kind of equilibrium growth, as in the “golden rule,” in which the propensity to save is such that per capita consumption is equalized across generations. This is obviously not what the classical economists meant by the stationary state.

STATISM

Statism is a more complex, quirky phenomenon than is often supposed. It is a more cerebral, less emotive concept—and a more recent one—than nationalism, patriotism, and xenophobia. Quentin Skinner, a prominent contemporary political theorist, regards the very use of the word *state* in early modern theory as a “decisive confirmation” of his thesis that “the state,” as opposed to “the ruler,” as the monopolizer of “legitimate” disposition over the means of violence, is foundational to what he terms “modernity” (Skinner 1978). Henceforward, rulers alternate in manning the state apparatus, but the state itself persists en *permanence*. Skinner explicitly follows Max Weber: “Modernity” involves the separation of the ruler from ownership of the means of rulership.

This leads to a problem. Whereas, in the words of Jens Bartelson (2001), “Skinner and other(s) … have accounted for the emergence of the modern state concept … it could be argued that their accounts … are themselves inherently statist, since they have posited a modern notion of the state as the end towards which early modern political reflection evolved…. It is as though all roads in the past led to Weber but none further beyond” (p. 9). Moreover, if one characterizes statism as predicated not just on the presence but also on the centrality of the modern state, one runs into an unexpected paradox. This paradox assumes a variety of guises, all of them marked by denial and avoidance. The USA Patriot Act of 2001, to give one egregious example, was designed to bolster the national security state, but did so by transposing “state” into “homeland.” The verbal legerdemain involved here is by no means without precedent: Euphemisms for “state” (Motherland, Fatherland, la patrie—the list goes on) have long abounded. This in turn is part of the reason why the unwieldy (and often inaccurate) composite, the “nation-state,” has become so familiar, as have such formulations as the United Nations, the International Monetary Fund, and the Communist International. None of these could have been engendered by nations; all are examples both of inter-state organization and, once again, of an intriguing, fastidious avoidance of the word “state.” Political scientists have proved adept at introducing semantically equivalent locutions for the state (e.g., the “governmental process,” the “political system”). These subterfuges are invariably unconvincing. By reintroducing the state through the back door, they inadvertently attest to the hold or centrality of a concept they had started out by trying to avoid. Not for nothing was there a recent debate within the reconcile reaches of political science about “bringing the state back in”: Where, one has to ask, did participants in this debate think it had ever gone away to?

But if the state was there all along, we must at this point ask questions about its oddly elusive centrality. Nothing sensible can be said about statism without doing so. As Bartelson (2001) states, “within large parts of our legacy of political theorizing, the state is both posited as an object of political analysis and presupposed as the foundation of such analysis…. [This] makes it inherently difficult to take political theorizing out of its statist predispositions” (p. 5). Anarchist theorizing, to take one extreme, fails at the level of significance in that “the state” is both the object and the condition of its critique (Thomas 1985). At another extreme, to regard “the state” as the telos (ultimate end) toward which political reflection as well as political innovation was moving would make early instances of state institution-building, such as cameralism, presentiments of statism too—which would make about as much sense as regarding the Magna Carta of 1215 as the fountainhead of present Western liberties. The state, one should remember, is an institution. Statism is a concept, one that would make of the state what it is not: the be-all and end-all of political life, or “the sole source of its intelligibility.”

States differ. All of them may appear as unitary entities when viewed from the outside, looking in: They are conditioned by the absence of their features—authority and sovereignty—in what is (incorrectly) called the “international” sphere. The state is also distinct from civil society, when viewed from the inside, looking out. The state and the international sphere, on the one hand, and the state and civil society, on the other, are binaries in which each term is always already defined in terms of the other term of the couplet. But it follows from none of this that states are best understood as constructs or resultants of parallelograms of forces that predated them, constructs that, once established, change the rules of the game once and for all. States are also entities that have tasks to perform—things to do, that is, other than satisfy definitional requirements. States do not often do these well. They make universalist claims on their own behalf while restricting popular participation in “their” affairs. Their record in addressing, let alone confronting, citizens’ claims are at best mixed. These claims are themselves not of a piece. Personal rights (such as freedom of speech and assembly) are distinct from political rights (which center around claims to participate in the workings of the state), and both are distinct in their turn from what T. H. Marshall (1964) calls the rights of “social citizenship” (guaranteed education, full employment, decent housing, free medical care—the foundation of the twentieth-century “welfare state”).

It is noteworthy that the early-twenty-first-century U.S. national security state (the “homeland”) trumps the rights of social citizenship (which have never counted for much in the United States) with a mixture of personal and political rights that are trumpeted and reified as the consummation of what is called “freedom,” this being one of
many stratagems to which modern states can, with frightening ease, resort. Statism is of great help to such sleight of hand. It is content to award the state a set of purely formal credentials. Citizenship as outlined above is, nevertheless, not a formal category but the site of substantive demands and rights. Because it is the state’s job to deliver on these, and to not fulfill formal definitional requirements, states on all but statist characterizations may be found wanting—and this gives everyone a great deal of work to do.

STATISTICAL EFFICIENCY
SEE Properties of Estimators (Asymptotic and Exact).

STATISTICAL NOISE
Statistical noise refers to variability within a sample, stochastic disturbance in a regression equation, or estimation error. This noise is often represented as a random variable.

In the case of a regression equation
\[ Y = m(X \mid \theta) + \varepsilon, \]
with \( E(\varepsilon) = 0 \), the random variable \( \varepsilon \) is called a disturbance or error term and reflects statistical noise. Noise in this context is usually viewed as arising from omitted explanatory variables; as such, the error term is a proxy for variables not included in the regression. Variables may be omitted from the regression for several reasons. The theory determining the behavior of the dependent variable \( Y \) may be incomplete, or perhaps some variables known to influence \( Y \) are unavailable to the researcher. Variables that have only slight influence on \( Y \) might be eliminated from the regression in order to maintain a parsimonious model.

If the conditional mean function \( m(x \mid \theta) \) is specified parametrically (e.g., as in ordinary least squares), the error term might reflect error in this specification, which is perhaps only an approximation to the true form of \( m(x \mid \theta) \).

Even if the regression equation includes all relevant variables, and if the conditional mean function is correctly specified, the error term may reflect either measurement error in \( Y \) or intrinsic randomness in \( Y \). Intrinsic randomness might be the result of nonsystematic variation in human behavior if \( Y \) describes the action of individuals. Tastes, preferences, and the like may be explained partly by other variables, but notions of bounded rationality in microeconomic theory suggest that some behavior is inexplicable.

In the typical estimation paradigm, a finite sample of size \( n \) is drawn and used to compute an estimate \( \hat{\theta} \) of some quantity \( \theta \) that is of interest. Even if the estimator is statistically consistent, the estimate that is obtained will typically differ from the true quantity \( \theta \) because the researcher does not have an infinite amount of data, but only a finite sample. The difference between \( \hat{\theta} \) and \( \theta \) can be expressed by writing
\[ \hat{\theta} = \theta + \varepsilon, \]
where again \( \varepsilon \) represents statistical noise, which can be positive or negative. In principle, one could draw many samples of size \( n \) and compute estimates of \( \theta \) from each sample; each estimate would differ from the true \( \theta \). These random differences constitute a form of statistical noise. In this case, the noise arises from the fact that each sample of size \( n \) will not have exactly the same characteristics (e.g., the means, variances, etc. of observations on individual variables will differ across samples, and will also differ from the mean, variance, etc. of the underlying population from which the data are drawn).

Statistical noise plays a large role in determining what can be learned from a sample of data in any estimation setting. The variance of regression residuals determines, in part, the goodness of fit of an estimated regression line as well as the variance of estimators of regression parameters and other quantities. The variance of an estimator determines the precision of estimates that are obtained from data, which in turn affects the width of confidence intervals and the ability to reject null hypotheses of the form \( H_0: \theta = 0 \). Statistical noise is often assumed to be normally
distributed, but this assumption is inappropriate in many settings.

STATISTICS
Statistics is a discipline that deals with data: summarizing them, organizing them, finding patterns, and making inferences. Prior to 1850 the word statistics simply referred to sets of facts, usually numerical, that described aspects of the state; that meaning is still seen in the various sets of government statistics, for example the monthly report on the nation's unemployment rate and the voluminous tables produced in the wake of each decennial census. During the twentieth century, as a result of the work of Karl Pearson, Ronald Fisher, Jerzy Neyman, Egon Pearson, John Tukey, and others, the term came to be used much more broadly to include theories and techniques for the presentation and analyses of such data and for drawing inferences from them. Two works by Stephen Stigler, The History of Statistics: The Measurement of Uncertainty before 1900 (1986) and Statistics on the Table: The History of Statistical Concepts and Methods (1999) offer broad and readable accounts of the history of statistics.

Although often taught in departments of mathematics, statistics is much more than a branch of applied mathematics. It uses the mathematics of probability theory in many of its applications and finite mathematics and the calculus to derive many of its basic theoretical concepts, but it is a separate discipline that requires its practitioners to understand data as well as mathematics.

VARIABILITY
In a sense, statistics is mainly concerned with variability. If every object of the same class were the same, we would have no need for statistics. If all peas were indeed alike, we could measure just one and know all about peas. If all families reacted similarly to an income supplement, we would have no need to mount a large scale negative income tax experiment. If all individuals held the same opinion on an issue of the day, we would only need to ask one person's opinion and we would need to take no particular care in how we chose that person. Variability, however, is a fact of life and so statistics is needed to help reveal patterns in the face of variability.

Statistics is used in the collection of data in several ways. If the data are to be collected via an experiment, statistical theory directs how to design that experiment in such a way that it will yield maximum information. The principles of replication (to allow the measurement of variability), control (to eliminate known sources of extraneous variability), and randomization (to "even out" unknown sources of variation) as enunciated by Fisher in his 1935 book The Design of Experiments help ensure that if differences are found between those receiving experimental treatment(s) and those in control group(s), those differences can be attributed to the treatment(s) rather than to preexisting differences between the groups or to experimental error. If the data are to be collected via a sample survey, the principles of probability sampling ensure that the findings can be generalized to the population from which the sample was drawn. Variations on simple random sampling (which is analogous to drawing numbers out of a hat) take advantage of known properties of a population in order to make the sampling more efficient. The technique of stratified sampling is analogous to blocking in experimental design and takes advantage of similarities in units of the population to control variability.

Once data are collected, via experiments, sample surveys, censuses, or other means, they rarely speak for themselves. There is variability, owing to the intrinsic variability of the units themselves or to their reactions to the experimental treatments, or to errors made in the measuring process itself. Statistical techniques for measuring the central tendency of a variable (e.g., means, medians) clear away variability and make it possible to view patterns and make comparisons across groups. Measures of the variability of a variable (e.g., ranges and standard deviations) give information on the spread of the data—within a group and in comparisons between groups. There are also summarization techniques of correlation and regression to display the patterns of relations between variables—for example, how does a nation's GDP per capita relate to its literacy rate? These numerical techniques work hand in hand with graphical techniques (e.g., histograms, scattergrams) to reveal patterns in the data. Indeed, using numerical summaries without examining graphical representations of the data can often be misleading. Of course, there are many more complicated and sophisticated summary measures (e.g., multiple regression) and graphical techniques (e.g., residual plots) that aid in the summarization of data. Much of modern data analysis, especially as developed by John Tukey, relies on less conventional measures, on transformations of data,
and on novel graphical techniques. Such procedures as correspondence analysis and data mining harness the power of modern computing to search for patterns in very large datasets.

FREQUENTIST AND BAYESIAN INFERENCE

Perhaps the most important use of statistics, however, is in making inferences. One is rarely interested merely in reactions of subjects in an experiment or the answers from members of a sample; instead one wishes to make generalizations to people who are like the experimental subjects or inferences about the population from which the sample was drawn. There are two major modes of making such inference.

Classical or frequentist inference (the mode that has been most often taught and used in the social sciences) conceptualizes the current experiment or sample as one from an infinite number of such procedures carried out in the same way. It then uses the principles codified by Fisher and refined by Neyman and Pearson to ask whether the differences found in an experiment or from a sample survey are sufficiently large to be unlikely to have happened by mere chance. Specifically it takes the stance of positing a null hypothesis that is the opposite of what the investigator believes to be true and has set out to prove. If the outcome of the experiment (or the sample quantity) or one more extreme is unlikely to have occurred if the null hypothesis is true, then the null hypothesis is rejected. Conventionally if the probability of the outcome (or one more extreme) occurring when the null hypothesis is true is less than .05 (or sometimes .01), then the result is declared "statistically significant."

Frequentists also carry out estimation by putting a confidence interval around a quantity measured from the sample to infer what the corresponding quantity in the population is. For example, if a sample survey reports the percentage in the sample who favor a particular candidate to be 55 percent and gives a 95 percent confidence interval as 52 to 58 percent, the meaning is that a procedure has been followed that gives an interval that covers the true population percent 95 percent of the time. The frequentist does not know (and is not able to put a probability on) whether in any particular case the interval covers the true population percent—the confidence is in the procedure, not in the interval itself. Further, the interval takes into account only what is known as sampling error, the variation among the conceptually infinite number of replications of the current procedure. It does not take into account non-sampling error arising from such problems in data collection as poorly worded questions, nonresponse, and attrition from a sample.

In order for these mechanisms of classical statistics to be used appropriately, a probability mechanism (probability sampling or randomization) must have been used to collect the data. In the social sciences this caution is often ignored; statistical inference is performed on data collected via non-probabilistic means and even on complete enumerations. There is little statistical theory to justify such applications, although superpopulation models are sometimes invoked to justify them and social scientists often argue that the means by which the data were accumulated resemble a random process.

Since the 1970s there has been a major renewal of interest in what was historically called inverse probability and is currently called Bayesian inference (after the English nonconformist minister and—during his lifetime—unpublished mathematician Thomas Bayes [1701?–1761]). Admitting the experimenter's or analyst's subjective prior distribution formally into the analysis, Bayesian inference uses Bayes' theorem (which is an accepted theorem of probability for both frequentists and Bayesians) to combine the prior distribution with the data from the current investigation to update the probability that the hypotheses being investigated is true. Note that Bayesians do speak of the probability of a hypothesis being true while frequentists must phrase their conclusions in terms of the probability of outcomes when the null hypothesis is true. Further, Bayesians construct credibility intervals, for which, unlike the frequentists' confidence intervals, it is proper to speak of the probability that the population quantity falls in the interval, because in the Bayesian stance population parameters are viewed as having probability distributions. For a frequentist, a population parameter is a fixed, albeit usually unknown, constant. Much of the revival of interest in Bayesian analysis has happened in the wake of advances in computing that make it possible to use approximations of previously intractable models.

While the distinction between Bayesians and frequentists has been fairly sharp, as Stephen E. Fienberg and Joseph B. Kadane (2001) note the two schools are coming together, with Bayesians paying increasing attention to frequentist properties of Bayesian procedures and frequentists increasingly using hierarchical models.

Two much more detailed descriptions of the field of statistics and its ramifications than is possible here are given by William H. Kruskal (1968) and Fienberg and Kadane (2001).

STATISTICS IN THE SOCIAL SCIENCES
Social science research generally relies on statistical analyses for the understanding of behavioral phenomena. Data analysis generally begins with an examination of descriptive statistics, then proceeds to inferential statistics.

DESCRIPTIVE STATISTICS: CENTRAL TENDENCY AND VARIABILITY
The arithmetic mean is the most common measure of central tendency. It is calculated by adding all the scores in a distribution and dividing by the number of scores. A less frequently used average is the median; it is calculated by ordering the numbers by size and identifying the middlemost score. The least used measure of central tendency is the mode, the most frequently occurring score.

When scores fall in a normal distribution, the mean is the most useful average because it gives a good sense of typical scores and because researchers can use it in subsequent sophisticated statistical tests. However, if a group of numbers is non-normal or has extreme values, the mean may not give a good sense of typicality; extreme scores have an inordinate impact on the mean, elevating or reducing it to give a false sense of typical values. In such a situation, researchers may use the median. Finally, the mode can be useful when an investigator is interested simply in getting a count of the number of observations in a given category.

To get a sense of the degree to which scores disperse, researchers calculate a measure of variability. The most common measures of variability are the variance and the standard deviation (SD); the SD is the square root of the variance. The SD tells, on average, how far any given score is likely to fall from the mean. Researchers prefer these measures with the mean because they can be used with sophisticated data analyses.

When investigators compute the median, they are likely to make use of a different measure of variability, the semi-interquartile range (SIQR). To compute the SIQR, the researcher identifies the scores at the twenty-fifth and the seventy-fifth percentile ranks and averages the two.

The least sophisticated, and least employed, measure of variability is the range. It is simply the difference between the highest and lowest score. It is greatly affected by extreme scores, so the range does not provide a useful measure of the degree to which scores cluster.

A final type of descriptive statistic is the standardized score, commonly the z-score. A standardized score indicates how far a given number in a distribution falls from the mean in standard deviation units. Thus, if a score fell one standard deviation above the mean, its standardized z-score would be +1.00. Or if a score fell half a standard deviation below the mean, its z-score would be −0.50. This descriptive z-score is used differently from the inferential statistic by the same name.

INFERENTIAL STATISTICS FOR TESTING DIFFERENCES BETWEEN MEANS
After an assessment using descriptive statistics, researchers conduct inferential tests designed to determine whether the obtained results are likely to generalize beyond the sample of subjects tested. Most of the statistics are based on certain assumptions regarding the data. In order for the tests to be maximally informative, data should be normally distributed and the variances of different groups should be equal. For some tests, there is an additional assumption of
equal sample sizes across groups. Although the tests are robust enough to permit some violation of assumptions, the greater the departure from the assumptions, the less optimal the information provided by the tests.

The most commonly used statistical tests in the social and behavioral sciences are the analysis of variance (ANOVA) and related tests, including the Student’s t-test; Pearson product-moment correlation; regression analysis; and the chi-square test. All of these except the chi-square test fall conceptually within the domain of the general linear model (GLM). ANOVA is a specific case of linear regression that is, in turn, a special case of the GLM. The basic premise of the GLM is that one can express the value of a dependent variable as a linear combination of the effects of a set of independent (or predictor) variables plus an error effect.

For historical reasons, researchers have treated ANOVA and related models and linear regression as different statistical approaches. Theoretically, these various tests are closely related, but in application, they are algebraically different. Hence, many researchers have not known of the close relation between them. As computer-based analyses have become nearly ubiquitous, however, a merging of the different approaches has begun (Howell 2007).

Researchers use the ANOVA and the Student’s t-test to assess whether reliable differences exist across groups. Historically, the t-test is the older of the two approaches, but the ANOVA is used more frequently. The two tests lead to identical conclusions. In fact, for a two-group t-test, there is an identity relation between an obtained t-value and the F-value, namely, $t^2 = F$.

The z-test is conceptually similar to the t-test, addressing the same questions, but is much less frequently used because the z-test requires that the investigator know the population mean and variance (and standard deviation). The t-test requires only estimates of the population mean and standard deviation, which the researcher can discern from the data. It is rare for researchers to know the population parameters.

The ANOVA is useful for comparing means of multiple groups in studies with a single independent variable and for comparing means of two or more groups in studies with multiple independent variables. The advantage of ANOVA for single-variable research is that it permits a global assessment of potential differences with a single test. The advantage of ANOVA with multiple independent variables is that the investigator can spot interactions among variables.

The ANOVA lets the researcher know if means of any two groups differ reliably, but it does not specify exactly which of the means differ. In order to determine which of multiple means differ from one another, researchers employ post hoc analyses. When a study has multiple dependent variables, or outcome measures, researchers use an extension of the ANOVA, the multivariate analysis of variance (MANOVA).

**INFERENTIAL STATISTICS FOR IDENTIFYING RELATIONS AMONG VARIABLES**

Sometimes investigators are interested in whether two factors covary. That is, is there an association between them such that by knowing a value of a measurement on one variable, one can make a reasonable prediction about the value on the second variable? Researchers use the Pearson product-moment correlation to identify the strength of an association between variables and regression analysis for making predictions.

Correlations can be positive, wherein as the score by a subject on one variable increases in magnitude, so does the magnitude on the second variable. Correlations can also be negative, as when increasing scores on one variable are paired with decreasing scores on the other variable. Or there can be no relation between the two variables. The sign, positive or negative, of the correlation does not indicate the strength of a relation, only the relative direction of change of scores on the two variables. The strength of a relation between variables is signaled by the absolute value of the correlation coefficient. These coefficients range from $-1.00$ to $+1.00$.

In some research, the investigator tries to predict a dichotomous outcome (e.g., success versus failure). In this instance, the appropriate test is known as logistic regression.

**NONPARAMETRIC STATISTICS**

The commonly used statistical tests make assumptions about characteristics of data. When the assumptions are not tenable, researchers can use nonparametric statistics, sometimes called distribution-free tests because they do not make any assumptions about the nature of the data in a distribution. Their advantage is that they do not require that data be normally distributed or that different groups have equal variability. Their disadvantage is that they discard some information in the data; thus they are, statistically speaking, less efficient. There are nonparametric statistics that correspond to the commonly used parametric tests.

When a two-sample t-test is inappropriate because of the nature of the distribution of scores, researchers can use either the Wilcoxon rank-sum test or the Mann-Whitney U. Instead of a one-sample paired t-test, one could use Wilcoxon’s matched-pairs signed-ranks test or the sign test.

A replacement for the ANOVA is the Kruskal-Wallis one-way ANOVA for independent samples. When there
are repeated measurements of subjects, Friedman’s rank test for \( k \) correlated samples can be appropriate to replace the ANOVA.

When a study involves observations of the frequency with which observations fall into various categories, a common nonparametric test is the chi-square test. There are two varieties in common use, depending on whether the research design involves a single variable or two variables. The one-variable chi-square is a goodness of fit test, indicating whether the predicted number of observations in specified categories matches the observed number. The two-variable chi-square test assesses whether the frequencies of observations in different categories are contingent upon values of the second variable.

**HYPOTHESIS TESTING**

The logic of inferential tests of statistical significance is to establish a null hypothesis, \( H_0 \), that specifies no relation between variables or no differences among means, then to see if there is enough evidence to reject \( H_0 \) in favor of the experimental (or alternate) hypothesis. Rejection of \( H_0 \) is associated with an a priori probability value that the researcher establishes. Most researchers select a probability value of .05, meaning that they will reject \( H_0 \) if the probability of having gotten the obtained results is less than 5 percent if \( H_0 \) is actually true.

When rejecting \( H_0 \), researchers note that their results are statistically significant. Nonscientists often erroneously interpret the word significant to mean important. This technical wording is not intended to convey a sense that the results are important or practical. This wording simply means that the results are reliable, or replicable.

One objection to null hypothesis testing is that the cutoff for statistical significance is traditional and arbitrary. A probability value of .051 conveys much the same effect as a statistically significant value of .05, yet researchers have traditionally claimed that the slightly higher probability value puts their results into a different category of results, one reflecting no interesting findings and insufficient information to reject \( H_0 \).

The approach of most researchers is to question the likelihood of obtaining the results if \( H_0 \) is true. Thus, any conclusion specifies how rare the results were if the \( H_0 \) is true, but, logically, this approach says nothing about whether \( H_0 \) actually is true. The logic of traditional tests of the null hypothesis is often confused with the question of whether \( H_0 \) is true, given the results that were obtained. These two questions are conceptually very different. As a result, the traditional tests also say nothing about whether an experimental hypothesis, presumably the one of interest, is true.

Controversy currently exists regarding the adequacy of such tests of the null hypothesis. Theorists have argued that \( H_0 \) is, strictly speaking, never true. That is, there will always be differences across groups or relations among variables, even if the differences are small or the relations weak. As a result, researchers have proposed alternate strategies for answering research questions.

One suggestion is to report effect sizes rather than simple probability values. Generally speaking, there are two families of effect sizes, \( d \)-families for questions of difference and \( r \)-families for questions of association (Rosenthal 1994). In an experiment, an effect size is a statistic that assesses the degree of variability due to treatments compared to variability caused by unknown factors like measurement error. A common measure of effect size when two groups are compared is Cohen’s \( d \). For more complex designs, investigators assess effect size through measures like eta-squared, \( \eta^2 \), and omega-squared, \( \Omega^2 \).

Effect sizes in correlational analyses include \( r^2 \), which indicates the percentage of common variability among correlated variables. (In linear regression analysis, \( r^2 \) has a different meaning, relating to error in predicting the value of a criterion variable from predictor variables. It is conceptually related to the similarly named statistic in correlations.)

A different supplement to traditional hypothesis testing involves the use of confidence intervals (CI). A CI specifies the range of scores that can be considered plausible estimates of some population parameter. The parameter most often estimated is the mean. Thus a CI for a mean gives the investigator a sense of values of the population mean that seem reasonable, given sample values.

Some investigators have suggested that CIs be used to increase the information provided by null hypothesis testing because CIs give information about potential effect sizes, about the statistical power of a study, and about comparability of results across different studies. As with any emerging statistical technique, there are controversies associated with the use of CIs (Cohen 1994; Cumming and Finch 2005), including the fact that researchers in the social and behavioral sciences are still relatively untutored in the use of CIs (Belia et al. 2005).

One recent approach to hypothesis testing has been to replace the traditional probability value (i.e., what is the probability that the result occurred given that \( H_0 \) is true?) with the probability that an effect can be reproduced if a study were replicated (Killeen 2005). Theorists have argued that social and behavioral researchers are typically interested in whether their effects are real and will replicate, not whether the researcher can reject a statement of no effect. Thus it makes more sense to use a statistic that allows a prediction about how likely a result is to recur if a study is repeated.

A final, alternate approach to hypothesis testing involves Bayesian statistics. This approach relies on an
investigator’s prior knowledge and beliefs about the outcome of research. Given certain a priori assumptions, it is possible to compute the probability that $H_0$ is true, given the data, instead of merely the likelihood of obtaining the data, assuming that $H_0$ is true. Unfortunately, accurate probability values that would make the Bayesian approach feasible in the social and behavioral sciences are very difficult to ascertain, so few researchers have adopted this approach.

SCALES OF MEASUREMENT

The noted psychologist S. S. Stevens (1906–1973) identified four scales of measurement, each in increasing order of mathematical sophistication. Nominal scales are simply categorical (e.g., female-male). Ordinal scales are ordered in magnitude, but the absolute magnitude of the difference between any two observations is unspecified (e.g., the number of votes of the first-, second-, and third-place candidates in an election). With interval scales, a given difference between any two scores means the same at all points along the scale (e.g., the difference on a seven-point rating scale from one to two is equivalent to the difference between six and seven). A ratio scale involves the equality of differences between scores but also equality of ratios among scores (e.g., a task taking four seconds requires twice as much time as a task taking two seconds, and ten seconds is twice as long as five).

Behavioral researchers have sometimes claimed that parametric statistics require interval or ratio data. In reality, determining the scale of measurement of data is not always straightforward. Furthermore, statisticians do not agree that such distinctions are important (Howell 2007; Velleman and Wilkinson 1993). In practice, social researchers do not pay a great deal of attention to scales in determining statistical tests. Furthermore, some tests that purport to be useful for one type of scale (e.g., the phi coefficient for categorical data) are actually algebraic variations on formulas for parametric tests (e.g., Pearson’s $r$).

STEADY STATE

The concept of the “steady state” refers to a long-term, dynamic equilibrium, where diminishing returns have exhausted all the gains from capital deepening (i.e., increasing capital per worker). In the absence of technological progress, growth in per-worker output stops. A related concept of “dynamic equilibrium” was central to classical theory, particularly to David Ricardo’s growth theory. This dynamic equilibrium was called the “stationary state.” In the stationary state, all growth ends; both income and the size of the population are static. The stationary state occurs because diminishing returns in agriculture eventually lead to the end of growth. In this state the rate of profits is driven to zero, and rent captures all the economic output in excess of the output required to support the population at a subsistence wage rate. Policy
proposals were often justified in part by whether they would postpone the emergence of the stationary state.

After a century of neglect, interest in growth theory reemerged with the Harrod-Domar model, which was developed independently by Roy Harrod in 1939 and Evsey Domar in 1946. This model did not have a dynamic equilibrium, however, because it did not allow for the possibility of diminishing returns. It was not until the Solow model emerged in 1956 that a dynamic equilibrium was introduced into neoclassical economics. The steady state in the Solow model occurs because the production function has diminishing returns. In this model, growth potentially has three sources: growth in capital per worker, growth in the labor force, and technological change. The latter two sources of growth are exogenous and are constant, as is the saving rate. For a linearly homogeneous production function, growth rates will converge to a steady-state growth rate, where all the positive effects of saving and investment on growth have been exhausted and where only the rate of population growth and the rate of technological progress impact the growth rate. This steady-state growth rate is expressed as $g = \dot{Y}/Y = \lambda + n$, where $g$ is the rate of growth of income (GDP), $\lambda$ is the rate of technological change, and $n$ is the rate of growth of the labor force.

This steady-state growth rate can best be understood by considering a linearly homogeneous production function, $Y = F(K, L)$, where $K$ is capital and $L$ is labor. Output per unit of labor is $Y/L = y = f(k)$. The labor input can increase either because the number of workers, $N$, rises, or because Harrod-neutral technological change makes each worker more productive. Assume that $N$ grows at a constant rate, $n$, and that there is a constant rate of technological change, $\lambda$. Then $L$ will grow at the rate $n + \lambda$. With a constant marginal and average propensity to save and invest, $s$, capital per worker, $k$, will change by $\dot{k} = sY - (n + \lambda + \delta)k$, where $\delta$ is the rate of depreciation. Increases in $k$ will increase $\dot{Y} = f(k)$, and $k$ will increase if $sY > (n + \lambda + \delta)k$. In other words, there will be capital deepening, which increases capital per augmented worker, $L$, if investment is sufficient to offset depreciation and provide each augmented worker with the same capital as before.

Policies that affect saving and investment will only have a temporary impact on growth, but since $s$ does not affect steady-state growth, policy will have no impact on growth in the long run. Policy will, however, affect the steady state level of income per augmented worker, $y$. Consider an economy that is at a steady state. An increase in the saving rate will temporarily increase the growth rate because it will increase $sy$. Eventually a new steady-state level of $y$ is reached and the growth rate will fall to its original level of $\lambda + n$. The economy is said to conditionally converge to an equilibrium $y$. The level of $y$ is conditional on the saving rate, the labor force growth rate, and the technology.

Endogenous growth models have challenged this notion of the steady state by introducing models where policy matters in the long run because certain types of saving and investment affect $\lambda$ through positive externalities. If these externalities exhibit constant returns, then policies that affect the saving rate will influence steady-state growth, and growth rates will not converge. Convergence is one of the most tested implications of the neoclassical steady state. If all countries share the same technology because knowledge is freely available, then per capita income should depend only on the rate of saving. Furthermore countries or regions that were late to develop should conditionally converge to countries that began to develop earlier. In other words, everything else being equal, poor countries should experience faster growth than rich countries. Robert Barro and others have tested for this convergence in cross-sectional estimates of growth. One of the explanatory variables is real per capita income for some earlier year. A negative coefficient for past income is evidence that convergence is occurring. Many empirical studies have found a negative coefficient, indicating conditional convergence, but they have also found that the rate of convergence is slow.

Conditional convergence does not necessarily imply a narrowing of gaps in per capita income between rich and poor nations. Many countries, both rich and poor, may be at or close to their conditional steady state, where per capita income is determined by structural variables, such as population growth rates, saving rates, and structural and institutional factors that determine $\lambda$, the rate of technological change (see Jones 1997; Darity and Davis 2005). Structural, institutional, and historical differences are receiving attention in the literature on economic development (see Grabowski, Self, and Shields 2007).

Steel Industry

The steel industry has a rich history. It exhibited remarkable technological dynamism and entrepreneurship and enjoyed significant economic, political, and strategic importance. With globalization and emergence of high technology sectors the industry has lost its clout. Western nations no longer dominate the industry due to changing costs and diffusion of technology and favorable government policy by selected high growth developing countries.

Rise of an Industry

The modern steel industry is inseparable from the second Industrial Revolution of the nineteenth century. From simple, small-batch production, new technologies such as the Bessemer process (developed in England in 1854) contributed to the mass production of steel. The industry diffused throughout Europe and the United States. The depression of the 1890s and subsequent mergers consolidated the American industry. In 1901 U.S. Steel, then the world’s largest company, was formed. Scale of production increased dramatically in the twentieth century with large-scale blast furnaces to melt iron ore, its reduction in open hearth furnaces, followed by larger and more efficient basic oxygen furnaces (developed in Austria in 1954), continuous casting of molten steel, and port-based mills (in Japan and South Korea), which relied on massive ships capable of transporting imported raw materials and exports of finished steel products inexpensively. In the United States in the 1980s Kenneth Iverson adopted German innovations in electric arc furnace (EAF) technology. These mini-mills relied on recycled scrap or natural gas-based directly reduced iron (DRI) and thin slab casting. Mini-mills’ smaller scale added to its flexibility and competitiveness compared to blast furnace–based integrated producers.

The geographical location of steel mills was dictated by the availability of coal and iron ore. For the United States in the mid-1800s coal fields in eastern states such as Pennsylvania, Ohio, New York, and New Jersey attracted major iron works. Similarly, the availability of iron ore and coal around Birmingham, Alabama, and later in the late nineteenth century in Minnesota and Michigan influenced the location of steel mills in the Great Lakes region with Chicago as a major market. Such patterns have been found in other countries such as Brazil and India where mills were located near mines. However, in East Asian countries such as South Korea, Taiwan, and Japan, devoid of raw materials, a new pattern of plant location emerged, targeting coastal locations to source raw materials from and export finished steel to the world economy.

The post–World War II (1939–1945) American industry was characterized by oligopolistic competition at home, slow technological change, and little international competition. A handful of firms led by U.S. Steel dominated the industry. Supportive Keynesian policies propped up the U.S. economy, maintained industry profits, and accommodated high wages for steel workers. A major steel strike in 1959 paralyzed the economy, which was soon followed by brief controls of steel prices during the Vietnam War under the Kennedy administration (1961–1963) to stem inflationary pressures. John F. Kennedy asked steel workers to restrain their wage demands on the condition that steel corporations such as U.S. Steel would not raise prices. While workers kept their part of the bargain the companies did not as prices increased by $6 a ton. An infuriated Kennedy found such action as “wholly unjustifiable and irresponsible defiance of the public interest” (Kennedy 1962). Such price controls have been maintained worldwide through subsidies and public ownership because of the industry’s dense intersectoral linkages. Not only are investments and employment encouraged in other industries but also economy-wide inflation is restrained. Steel is also a strategic industry with direct links to the defense sector.

Government Policy and Shifts in the Industry

Strikes in the steel industry were commonplace as conflict over wages and working conditions became paramount under rapid growth. The violent Homestead strike of 1892 in Pennsylvania turned into a complex battlefield with Andrew Carnegie using scab African American labor to crush the largest craft union, the Amalgamated Association of Iron and Steel Workers. In 1919 steel workers fought U.S. Steel and the movement was labeled a “Red Scare,” unleashing an anti-Bolshevik and anti-radi-
Steel Industry

States inability. In Europe and in India, pro-labor social democratic governments and public ownership of many steel mills protected workers, while in South Korea unions were either banned or co-opted by the government-controlled Federation of Korean Trade Unions (FKTU), which was also infiltrated by the Korean Central Intelligence Agency. In the early twenty-first century, steel unions persist but most have lost their clout due to global competition from developing countries, declining membership, and the relative insignificance of the industry in economies driven by services and high technology. Unionization of American workers as a whole declined from 50 percent in the 1950s to about 13 percent by 2004.

Reconstruction of Western Europe and Japan and the rapid adoption of new steel technologies around the world eroded the American industry’s competitiveness. The industry has been protected and promoted by governments worldwide as it has dense backward (ore, coal, heavy equipment) and forward linkages (construction, machinery, automobiles, shipbuilding). Some of the leading steel firms in Western Europe, such as British Steel and French Usinor-Sacilor, have been state owned. In late industrializing countries state ownership was routine as part of their import substitution industrialization strategy. Steel Authority of India (SAIL) in India, Siderurgia Brasileira (SIDEBRAS) in Brazil, the highly successful Pohang Iron and Steel Corporation (POSCO) in South Korea, and China Steel Corporation (CSC) in Taiwan were all state-owned. The former Soviet Union, Eastern bloc countries, and China, though outside the capitalist world economy until the late twentieth century, also relied on the industry for national development. The American industry was caught off guard by new mills, often with newer technologies. Since the late 1950s, the United States has been a net importer of steel. By 1987 Japan and South Korea supplied 28 percent of U.S. imports, mostly in high value flat products, while Western Europe, saddled with excess capacity, had a similar U.S. share. In the mid-2000s imports constitute 21 percent of the U.S. market.

In periods of high economic growth steel unions in the United States secured high wages, exceeding the average industry wage. Employment in the industry ensured working-class members middle-class living standards. However, by the 1970s technological obsolescence in the United States, excess global capacity, and lower operating costs in East Asia and Brazil made American steel jobs insecure. As foreign companies targeted the large U.S. market in cyclical downturns, the United States adopted a variety of protectionist policies. It started with voluntary restraint agreements (VRAs) in 1968, then the Trigger Price Mechanism (TPM) during the Carter administration (1977), and additional VRAs during the Reagan, Clinton, and the Bush Sr. administrations (1982–1992). The TPM was designed to penalize countries selling below cost, while VRAs forced foreign firms to restrain exports to a preset market share. Plagued by cumulative losses, including large debts and pension fund obligations, these policies merely deferred restructuring but did not prevent plant shutdowns and investments in non-steel sectors. The ensuing production imbalances compelled U.S. producers to obtain new technologies from capital surplus Japanese producers to supply better quality steel to auto producers in the United States, including Japanese auto transplants, while debt-ridden countries such as Brazil sought foreign investments for steel exports. Unable to maintain the high-wage workforce, the American steel industry shed nearly 300,000 steel jobs over the past quarter century and consequently improved labor productivity considerably. U.S. productivity also increased due to the diffusion of mini-mills. With lower capital and labor costs than the integrated segment and the hiring of nonunion workers in the southern United States, about 54 percent of American steel is produced with mini-mill technology.

STATE OF THE INDUSTRY AND FUTURE TRENDS

In the mid-2000s the major steel-producing countries are China, Japan, the United States, Russia, and South Korea with 272, 113, 99, 66, and 48 million metric tons respectively. Major exporters are Japan, Russia, Ukraine, Western Europe, South Korea, and Brazil. The most noteworthy development is the unprecedented growth of the Chinese economy since economic liberalization in 1979. Not only does China produce two-and-one half times more steel than Japan, but between 1998 and 2004 Chinese consumption of steel increased from 111 to 265 million metric tons. High demand in China moderates competition arising from excess global capacity and could prompt occasional shortages. While there is considerable intra-European steel trade, Russia, Japan, and South Korea have found the Chinese market attractive.

Globalization and neo-liberal policies have increased steel trade, cross-national investments and mergers, and privatization of state firms. Mittal Steel, founded by an Indian entrepreneur, has become the world’s largest steel company through its acquisition of mills in the United States, Europe, Central Asia, and Mexico. In 2006 after many rebuffs, Mittal Steel acquired Arcelor, the world’s largest steel firm revenue-wise, located in Luxembourg. Arcelor itself is a product of a merger between Spanish Aceralia, French Usinor, and Luxembourg’s Arcobel. Arcelor-Mittal is the largest steel venture with considerable expansion plans in India and elsewhere. In 2005 POSCO of South Korea, with several steel ventures in Asia and Latin America, announced a $12 billion iron and steel project in India. With declining steel intensity (share of steel to gross domestic product) in mature economies.
such as the United States, the growth of services, high technology industries (the new economy), and material substitutions, the steel industry is unlikely to witness a major resurgence in OECD economies. Both investment requirements and environmental concerns have dampened construction of large steel mills. The Clean Air Act implemented by the U.S. Environmental Protection Agency has made substantial improvements in steel plant emissions. Smaller plants using alternative technologies are feasible, but the supply of scrap, natural gas, and electricity may limit their diffusion in developing countries.

As long as mature economies are saddled by excess capacity, trade conflicts will persist. The use of Section 201 to assist American steel workers allegedly injured by subsidized steel imports is perceived by foreigners to be hypocritical since trade barriers and bailouts of firms of their pension obligations slow industrial adjustment. Higher steel prices resulting from protection could lead to job losses in steel-using industries, benefiting shareholders rather than workers. In the end, shared global prosperity is likely to ease the adjustment process, while any slowdown in China will exacerbate the excess capacity problem. High growth developing or exporting countries such as China, India, and Brazil are good candidates for the future expansion of the industry, while Japan and South Korea will remain important global suppliers of steel and steel technologies.

STEEL, CLAUDE M.

1946–

One of the most influential social scientists of the past five decades, the American social psychologist Claude Mason Steele is best known for two conceptually related lines of research and theorizing: the effects of negative stereotypes on the achievement and identities of minorities and women and people's psychological adaptation to self-image threats. He has also conducted research on the psychological effects of alcohol consumption.

SELF-AFFIRMATION THEORY

In 1988 Steele published what would become the most widely embraced modification of Leon Festinger’s theory of cognitive dissonance, arguably social psychology’s most influential theory of human motivation. Festinger (1957) had proposed that when people become aware of holding two inconsistent cognitions (e.g., I smoke cigarettes and smoking is unhealthy), they are motivated to reduce the resulting psychological discomfort by restoring consistency (e.g., by persuading themselves that smoking is not really very harmful). Steele challenged the central tenet of dissonance theory—that people find inconsistency per se uncomfortable and have a fundamental need for consistency between cognitions. Steele proposed that people are bothered not by mere psychological inconsistency but by the negative portrayal of the self that the inconsistency implies. Like earlier dissonance revisionists (e.g., E. Aronson 1969), Steele stressed the critical role of the self-concept in mediating the induction and reduction of dissonance, but unlike them, he rejected any inherent human preference for consistency, relegating inconsistency to a mere signal that the integrity of the self-image is under threat. For Steele, the psychic origin of dissonance phenomena is the actor’s desire to maintain a sense of global “self-integrity,” and this desire supersedes any need for consistency.

Steele further posited a self-system comprising self-conceptions, values, talents, and so on, which make up a pool of resources upon which the actor may draw to restore a sense of self-integrity when self-image threats arise. This fact, Steele proposed, gives the actor a great deal of flexibility in responding to self-threats. Employing Festinger's oft-used example of the cigarette smoker who reduces dissonance by downplaying the risks of smoking,
Steele argued that the smoker can maintain a sense of global integrity by reminding himself or herself of virtues in other domains of his or her life (I’m a great father, I’m a valuable member of the church, etc.). Such self-affirmations restore global self-esteem, thus allowing the individual to tolerate the self-threat implied by smoking despite the evidence that smoking is unhealthy.

Steele and his students tested the self-affirmation formulation by replicating standard dissonance paradigms in which a person is induced to engage in dissonance-arousing behavior (choosing between equally attractive gifts, writing a counter-attitudinal essay in support of an unpopular social policy, etc.) and then has his or her attitudes (e.g., toward the gifts or social policy) measured. If participants were given a self-affirmation of some sort (e.g., writing a few sentences about an important value), they showed no evidence of dissonance; in a wide variety of studies (Steele 1988), self-affirmations eliminated the attitude change that typically results from inducing dissonance.

Self-affirmation became influential as much for its highly transportable methodological paradigm—using value affirmations, for example—as for its theoretical alternative to dissonance. Examining the role of self-esteem threat has since become a thriving enterprise, as researchers can easily induce self-affirmation into the study of a variety of social-psychological phenomena, such as persuasion (e.g., Cohen, Aronson, and Steele 2000), prejudice (e.g., Fein and Spencer 1997), health (e.g., Creswell et al. 2005), and underachievement (e.g., Cohen et al. 2006). Although debate still continues on the role of inconsistency in cognitive dissonance, self-affirmation theory has established itself as a staple in current social psychology.

STEREOTYPE THREAT
Dissatisfied with the standard explanations for African Americans’ lagging test scores and achievement and viewing many phenomena through the hospitable lens of self-affirmation theory, Steele proposed a social-psychological alternative to the standard explanations that focused either on poverty or genetic differences in average intelligence. Steele proposed that black students face a self-threatening situational predicament that occurs as a result of their awareness of unflattering racial stereotypes. In a widely read article published in the *Atlantic* (Steele 1992), he proposed the possibility that African Americans are hampered by the stigma of intellectual inferiority—a phenomenon that later came to be called “stereotype threat” (Steele and Aronson 1995). In situations where the stereotype is applicable, such as during an intelligence test, African Americans face an extra psychological burden not felt by a comparable white student taking the same test, a sense of risk that the test may confirm a racial inferiority coupled with a heightened motivation to disprove the stereotype. Such a situation, Steele argued, generates anxiety, distraction, and other psychological impediments to test performance. Steele further proposed that, over time, students would defend against stereotype threat by disidentifying with academics, that is, reducing the extent to which they based their self-esteem on doing well academically.

A series of experiments performed with Joshua Aronson (Steele and Aronson 1995) offered strong support for the predictions about test performance. In each of the experiments African American college students performed significantly better on a standardized verbal test when the test was presented in a way that minimized the concern with confirming the stereotype. For example, in one experiment the test takers were told that the test was either a measure of their intelligence or that it was a nonevaluative laboratory problem-solving exercise. While this difference had no effect on white test takers, African American test takers performed nearly twice as well when the test was portrayed as nonevaluative.

These experiments drew national attention among educators and were referred to in two U.S. Supreme Court cases debating the use of affirmative action policies in hiring and college admissions. A publicized disagreement about the wisdom of affirmative action between Steele and his twin brother, Shelby Steele, the noted conservative scholar, drew additional attention to the research. Subsequent research confirmed the utility of the theory for understanding gender gaps in mathematics achievement, demonstrating that stereotype threat had similar effects on the mathematics performance of females (Spencer, Steele, and Quinn 1999).

In the decade after 1995 well over a hundred replications of stereotype threat effects on test performance were published, marking it as one of the most influential theories in the history of social psychology. Critics of the theory debate the degree to which stereotype threat underlies test-score gaps in the real world, but the theory has generated a handful of successful intervention studies that demonstrate that by reducing stereotype threat, race and gender test-score gaps are significantly reduced (Aronson, Fried, and Good 2002; Cohen et al. 2006; Good, Aronson, and Inzlicht 2003).

ALCOHOL MYOPIA
Steele and his students also conducted research on the psychological effects of alcohol consumption, documenting what they referred to as “alcohol myopia,” (Steele and Josephs 1990), the effect of narrowing the drinker’s focus upon immediate events and stimuli and reducing focus upon distant events, stimuli, or thoughts. Steele and his students documented that this narrowed focus plays a role...
in alcohol's well-known reduction of social inhibitions and reduction of emotional stress. After holding positions at the University of Utah, the University of Washington, the University of Michigan, and Stanford University, Steele became the director of the Center for the Advanced Study in the Behavioral Sciences.

**STEINEM, GLORIA**

1934–

Gloria Steinem, a leader in the twentieth-century struggle for women's rights, was born on March 25, 1934, in Toledo, Ohio. Because of her father's penchant for traveling to warmer climates each winter, Steinem and her sister, Suzanne, had little time for formal schooling. Her mother, who had been educated as a teacher, provided some homeschooling for the girls, long before homeschooling was widely accepted. When Steinem was eleven years old, her parents divorced, and with her older sister away at college, Steinem was left alone to care for her mother, who suffered bouts of deep depression, accompanied by dementia. At seventeen, Steinem went to live with Suzanne in Washington, D.C., where she finished high school and completed her education at Smith College, where she graduated Phi Beta Kappa in 1956.

After spending a year in India, Steinem returned to the United States and worked as a public relations officer for a group later associated with the Central Intelligence Agency (CIA), although she claims to have had no knowledge of the association at that time. She later wrote for *Esquire*, *Glamour*, and *Show* magazines, where her exposé of life as a Playboy bunny earned her not only accolades but also fame. At *New York* magazine she worked with many of the budding writers of the New Journalism movement, including Tom Wolfe, Norman Mailer, and Gay Talese.

When the National Organization for Women was founded in 1966, Steinem, like many other women, saw the movement as a vehicle for white, middle-class housewives wanting to achieve independent goals outside traditionally male-controlled marriage. She saw no merit in the
movement for herself, a single sophisticate, working in New York. But in 1969, Steinem attended a rally on abortion held by the feminist organization the Red Stockings, and after hearing other women detail the pain and humiliation they had endured, she had an epiphany. She had had an abortion herself and was harshly judged by the medical personnel who attended her procedure. Stories told by the women at the rally were even more horrific and included tales of emotional and physical pain and even death. Through the rally, Steinem came to see that not only married middle-class white women, but all women, including women of color, deserved to be treated as individuals, with rights equal to those enjoyed by men.

From that time forward, Steinem would devote much of her time and energy to furthering the cause of “reproductive freedom” and spoke at rallies around the country, recruiting women for the cause. She was a major catalyst in the movement’s long-term success and provided a strong voice in the ongoing struggle through Ms. magazine, which she and her partners founded in 1971.

By that time, Steinem had also become respected as a political writer and activist, and in 1972 she helped found the Women’s Action Alliance. She backed presidential candidates Shirley Chisholm and George McGovern, for whom she wrote several speeches. She also wrote five books, Outrageous Acts and Everyday Rebellions (1983), Marilyn: Norma Jeane (1986), Revolution from Within: A Book of Self-Esteem (1992), Moving Beyond Words (1994), and Doing Sixty and Seventy (2006).

Though she was credited with saying that “a woman needs a man like a fish needs a bicycle,” Steinem was not the originator of this phrase. She told Time magazine in 2000, “In fact, Irina Dunn, a distinguished Australian educator, journalist and politician, coined the phrase back in 1970 when she was a student at the University of Sydney.” Yet, the quip did define Steinem’s outlook on marriage during her time and energy to furthering the cause of “reproductive freedom” and spoke at rallies around the country, recruiting women for the cause. She was a major catalyst in the movement’s long-term success and provided a strong voice in the ongoing struggle through Ms. magazine, which she and her partners founded in 1971.

By that time, Steinem had also become respected as a political writer and activist, and in 1972 she helped found the Women’s Action Alliance. She told Time magazine in 2000, “In fact, Irina Dunn, a distinguished Australian educator, journalist and politician, coined the phrase back in 1970 when she was a student at the University of Sydney.” Yet, the quip did define Steinem’s outlook on marriage until 2000, when she married David Bale, a British entrepreneur and avid animal rights activist. The marriage, however, was to be short-lived. Bale died of brain cancer at the end of 2003, leaving Steinem to her lifelong quest of helping women find personal power and inner peace.

STEM CELLS
A stem cell has two special qualities: the ability to produce offspring of itself indefinitely, and the ability to differentiate into different types of specialized cells. “Adult” stem cells are found in various organs of fully formed organisms. For example, umbilical cord blood and bone marrow contain stem cells capable of producing the various cells found in the blood, such as red blood cells, white cells, and platelets.

Public debate about ethical, social, religious, and legal issues involving stem cells has centered on a different kind of stem cell, so-called embryonic stem cells, usually obtained from excess embryos created by in vitro fertilization (IVF), but sometimes created specifically for research or therapeutic purposes. These human embryonic stem cells (hESCs) have the capacity to form any tissue in the body; that is, they are totipotent.

HESCs are of scientific and medical interest for three reasons: (1) they provide an opportunity to do laboratory research on normal and abnormal differentiation; (2) they provide an opportunity to test experimental therapies, including drugs and genes, at a cellular level, without exposing living animals or humans to risk; (3) they present an opportunity to develop and transplant cell lines that can replace vital molecules such as insulin (for patients with diabetes mellitus) or dopamine (for patients with Parkinson’s disease), or to replace damaged tissue in the heart, nervous system, or elsewhere.

HESCs from residual IVF embryos are unlikely to be sufficient for all research and therapeutic interests. If, for example, stem cells are to be useful in treating diabetes, it will be important to create a cell line that is genetically identical to the recipient, so that it will not be rejected after transplantation. This can be accomplished by removing the nucleus of an egg, replacing it with the nucleus from a cell obtained from the potential recipient, and allowing the egg to grow to a stage when stem cells can be removed. This is called “somatic cell nuclear transfer” (SCNT).

SCNT is also of interest for laboratory research on genetic disorders such as cystic fibrosis or Tay Sachs disease. An embryo is created using the nucleus from a somatic cell of a patient with the disorder being studied, and then stem cells with the abnormal gene are obtained from the early embryo. This is sometimes called “research cloning.” SCNT for the purpose of creating a cell line that would be used for treatment is sometimes called “therapeutic cloning.”

Objections to research involving hESCs involve several concerns. First, some believe that an embryo has the same moral status as a fully formed human and is entitled to the same protections. Destruction of an embryo, in this view, is morally equivalent to murder. Proponents of
hESC research point out that residual embryos are used only when the parents intend to destroy them anyway, and are not destroyed because of the interest in stem cell research. They also point out that tens of thousands of residual IVF embryos are destroyed annually without similar objection.

Second, opponents also argue that there are alternative approaches to obtaining totipotential stem cells, such as using adult stem cells. Most experts believe adult stem cells are not totipotential and therefore should not divert research funds from the more promising embryonic stem cells.

Third, opponents object to SCNT combined with hESC research because of concerns that it is a critical technical step for reproductive cloning, the creation of genetically identical replicas of existing persons. Advocates of hESC research argue that reproductive cloning is nearly universally opposed at the present time, largely because of concerns about biologic safety, and that “slippery slope” arguments are insufficient to prohibit research that can help alleviate suffering, disability, and death from diseases affecting large numbers of existing persons.

Fourth, concerns have been raised that the transfer of human cells into the developing brain of laboratory animals could result in an animal capable of human experience and therefore with moral status comparable to a human. Although most neuroscientists consider this to be unlikely, some groups have proposed prohibiting full gestation of nonhuman primates if human stem cells have been implanted in their central nervous systems early in embryonic development.

Governmental policies reflect a range of approaches in different countries and states, and policies within any jurisdiction are often in flux, subject to the success of politicians with various views. Some prohibit human embryonic stem cell research; some permit it but have restrictions on use of public funds; some permit research using existing embryos but prohibit creation of embryos for research; and some restrict somatic nuclear cell transfer because of concerns that it may accelerate human reproductive cloning.

STEPFORD WIVES

The 1975 film *The Stepford Wives* begins with photographer Joanna Eberhart (Katharine Ross) leaving the urban malaise of New York City with her two children and her husband Walter (Peter Masterson) and moving to the picture-perfect village of Stepford, Connecticut, ready to start life anew and raise their brood in peace and tranquility. Strong, intelligent, with an independent streak, Joanna, we learn, has been a proponent of equal rights for women if not a strident feminist, and she is surprised to find that the housewives she meets are throwbacks to the 1950s, obsessed with homemaking and wanting nothing more from life than to please their husbands. Only her like-minded friend Bobbie Markowitz (Paula Prentiss) appreciates that something is clearly wrong here. Bobbie, too, thinks that the wives of Stepford are behaving more like life-size Barbie dolls than women of their own generation, and Bobbie is suspicious as well of why all their husbands spend so much time at the local men’s association.

Gradually, Joanna learns. Threatened by the women’s liberation movement, the men of Stepford have taken matters into their own hands. They are doing away with their wives one by one and replacing them with “gynoids,” android duplicates. Unfortunately, by the time Joanna discovers this, Bobbie has become the latest of these “trophy wives,” and the movie’s epilogue, delivered at the supermarket no less, suggests a similar fate for Joanna.

Directed by Bryan Forbes and scripted by William Goldman, this first movie version of Ira Levin’s best-selling 1972 novel did very well at the box office, earning a substantial $4 million from its domestic release alone, and it introduced into the American lexicon the term *Stepford wife*, a phrase meaning not simply “mindlessly deferential” but also “robotically conformist.”

The 2004 remake, also titled *The Stepford Wives*, fared less well, both with critics and the public. Frank Oz, who was chosen to direct, and Paul Rudnick, who wrote the script, both were best known for their ways with a comedy, and together they created a broad, campy farce. In their version, Joanna Eberhart (Nicole Kidman) is a cold, driven television executive who has been fired when...
one of the reality shows she produces ends in disaster. Joanna and her ineffectual husband Walter, here a network vice president played by Matthew Broderick, move to a gated Connecticut community where they are immediately greeted by a Martha Stewart–perfect realtor, Claire Wellington (Glenn Close), and her husband Mike (Christopher Walken), who welcome them into their plastic paradise.

Once again, Stepford proves to be a community where all the women Joanna’s age seem to awaken each morning wearing makeup, wanting nothing more than to bake their brownies and scrub their toilets and be there at the door when hubby gets home. The husbands are different, however. Goldman’s script depicted the husbands as sinister, manipulative, eerily efficient corporate types, whereas Rudnick’s makes them out to be men whose masculinity has been diminished by the highly successful women they married.

Joanna cannot understand why these women have forfeited their careers and embraced a model of pliant domesticity last seen in the Eisenhower era. Only two others in Joanna’s circle think this is odd as well: a feminist author, Bobbie Markowitz, and half of a newly arrived gay couple, Roger Banister. Rudnick’s specialty is sarcastic dialogue, the piercing one-liner, and the movie is well cast in this regard, for Bette Midler (Bobbie) and Roger Bart (Roger) deliver their lines with perfect aim as if they were poisonous darts. It is a truly funny movie, and, to their credit, the filmmakers achieve this without mocking the original. There is little or no suspense in this version, however. Goldman’s script depicted the husbands as sinister, manipulative, eerily efficient corporate types, whereas Rudnick’s makes them out to be men whose masculinity has been diminished by the highly successful women they married.

Typically stereotype threat is examined by asking people to perform a challenging task that evaluates their ability in an area. Before the task, some people are given a prompt designed to activate a stereotype. For example, when women are reminded of the stereotype that men are better than women at math, they score lower on a difficult math test. Similarly African American students who are told that a test reflects their verbal ability perform worse on the test than do equally capable white students. Mere mention that the test diagnoses verbal ability is enough to conjure up a debilitating belief among some African American students that their score will be lower. But a person need not be socially stigmatized, feel intellectually inferior, or belong to a minority group to be vulnerable to stereotype threat. In one study, white men from a prestigious university were asked to take a difficult math test on which, some were told, Asians typically perform better. The men in this threat condition performed worse on the exam than did those who received no information about how others perform. Indeed stereotype threat can impair the cognitive functioning of anyone who is in a negatively

Stereotype threat

Sterotype threat is a term coined by social psychologists Claude Steele and Joshua Aronson that refers to the fear people experience when they are at risk of confirming a negative stereotype that is held about their group. This psychological threat can undermine successful performance of tasks and activities.

Stereotypes

Stereotypes constitute a person’s set of expectations about a social group’s characteristics, including traits, behaviors, and roles. They are the categorical associations perceivers make to group members based on their membership. Although cognitive in form, stereotypes are interlocked with affect and behavior: Along with prejudice and discrimination, stereotypes make up the tripartite foundation for the breakdown of intergroup relations.

Stereotyping stems from categorization processes that involve the self. Social identity theory contends that people conceptualize the self at different levels of inclusiveness that range from the subordinate to the superordinate. At each level of abstraction, the corresponding identity (personal, social, or collective self) is salient, with reference to each varying by context. In perceiving the self through a social identity, the person views the self as part of an in-group that is distinctive and, under many circumstances, more subjectively positive than out-groups. Self-categorization theory continues this narrative:

Researchers have suggested a number of ways in which people can offset the detrimental effects of stereotype threat. Leaders and decision makers, whether in schools or elsewhere, can emphasize cooperative working environments that reduce prejudice, foster trusting interpersonal relationships, and value others as individuals. Placing an emphasis on the malleable nature of academic ability will also help individuals see the potential for intellectual growth and academic success. Researchers have also shown that individuals who are good self-monitors—that is, those who are sensitive to their social surroundings and able to regulate their behavior to negotiate them—show resilience in the face of stereotype-threatening situations. Helping individuals to become self-affirming may provide them with an interior source of strength and assurance needed to withstand environmental stressors.

STEREOTYPES

Stereotyped group (e.g., drug users, the elderly, athletes, the economically disadvantaged).

Stereotype threat is situation-dependent and is not a general attitude or expectancy that affects individuals across contexts. A threatening situation can occur any time a negative stereotype is brought to mind, even when a person is alone. Experimenters have also shown that priming positive stereotypes about one’s group can actually enhance performance. In one experiment, for example, Asian American women performed well on a mathematics test when their ethnicity was made prominent, but poorly when their gender was made prominent.

What makes people vulnerable to the threat of fulfilling a stereotype? First, people are likely to experience a threat in those areas in which they care about performing well. When a woman who values success in math is being evaluated, she will feel more threatened by a stereotype than will someone who dismisses math as unimportant. Also at risk are people who feel a strong sense of identification with and attachment to their group. Merely having to indicate one’s race on the first page of an evaluation can be enough to activate a threat and impair performance. When one is in the numerical minority (e.g., the only African American student in a group of white students), group identity is made even more salient. People who expect discrimination or suspect that a stereotype may be valid are also more easily triggered by threatening situations.

The fear of confirming a negative stigma has been shown to lower students’ performance on items from the Graduate Record Examination (GRE), the Texas Assessment of Academic Skills (TAAS), Raven’s Progressive Matrices, and high school Advanced Placement (AP) exams. Stereotype threat has also been shown to limit important cognitive resources such as working memory and self-monitoring capabilities. Students who feel threatened may enlist strategies to safeguard their self-esteem, such as opting for less challenging school work, making excuses for their school failures, resisting feedback others give them about their work, or disassociating with school-related activities altogether. As a consequence, the effects of stereotype threat may be far-reaching, influencing placement in advanced classes, college admissions, people’s career choices, and, ultimately, their earnings. Some argue that stereotype threat is in part to blame for the black-white achievement gap prevalent in U.S. schools.

Researchers have suggested a number of ways in which people can offset the detrimental effects of stereotype threat. Leaders and decision makers, whether in schools or elsewhere, can emphasize cooperative working environments that reduce prejudice, foster trusting interpersonal relationships, and value others as individuals. Placing an emphasis on the malleable nature of academic ability will also help individuals see the potential for intellectual growth and academic success. Researchers have also shown that individuals who are good self-monitors—that is, those who are sensitive to their social surroundings and able to regulate their behavior to negotiate them—show resilience in the face of stereotype-threatening situations. Ellen L. Usher
Depersonalization of the self via in-group and out-group differentiation triggers group phenomena that include stereotyping.

Two principles of self-categorization theory structure stereotypes: comparative fit and normative fit. In the former, also known as meta-contrast ratio fit, the smaller the perceived intragroup difference in comparison to intergroup differences, the more the group embodies a coherent unit. Thus, people are categorized into groups that minimize within-group differences and maximize between-group differences. Furthermore, normative fit requires that these differences, both within and between, align with the perceiver’s normative beliefs about the group—that the group fits expectations. An interaction between comparative fit and normative fit processes guides stereotype construction. Under the first principle, within-group variability decreases, increasing perceived homogeneity between group members; under the second, perceived group categories reflect a perceiver’s expectations about that group or the content of normative beliefs.

A two-dimensional framework inherited from person perception literature illustrates the content of stereotypes. Person and group perception use two recurring dimensions that are variations of warmth/morality and ability/competence. One example, the stereotype content model, argues that stereotypes immediately answer two key questions for the perceiver: Do out-group members intend good or ill toward me and my group? and Are they able to act on these intentions? The answers to these questions produce prototypes in four quadrants: ambivalent (or cross-dimensional) stereotypes (e.g., elderly people are stereotypically nice but incompetent, rich people are stereotypically competent but not nice); stereotypically neither warm nor competent (e.g., poor people); and stereotypically both warm and competent (e.g., middle class).

UTILITY: FORM FITS FUNCTION
Because stereotypes stem from the differentiation of “us” from “them,” stereotype targets usually fall outside the cultural default (in the United States): not young, not white, not male, not heterosexual, not middle class, and not Christian. Groups whose members are the least (visibly) representative of the default receive the most stereotypes. The high prevalence of age, racial or ethnic, and gender stereotypes results in part from the speed of categorizing people on these dimensions.

Stereotyped targets are not exclusive to the visibly different. Stereotypes also form when a person perceives an illusory correlation between a group and a particular characteristic; in actuality, group membership and the characteristic might covary by chance or because of historical development, or not even covary at all, but perceiving a fundamental connection strengthens the stereotypic quality of the characteristic for that group. Stereotypes may reflect the perceiver’s knowledge of power relations in society. Some national stereotypes exemplify such contextual influences on stereotype formation, with perceivers relying on features of a nation—political, economic, religious, geographic, and status vis-à-vis one’s own nation, among others—to characterize its residents. Because they are shaped by the social context, stereotypes reflect cultural beliefs. As such, they shift over time—when social conditions change, societies update their stereotypes of groups because the social relations of those groups transform. As an example, many ethnic groups in the early twenty-first-century United States receive more favorable stereotypes than they did in the 1930s, including originally mistrusted immigrants (e.g., Irish, Italian, Jewish) who now join the mainstream.

Whatever their origins, stereotyping serves cognitive, motivational, and social purposes. For example, in the cognitive miser view, stereotyping saves mental effort. Facing cognitively overwhelming tasks and limited attention and effort, people rely on stereotypes to increase available on-line resources. People's social interaction priorities also influence stereotyping. Many models of stereotyping posit two modes of impression formation, with some models arguing for an either-or competition between the two, and others placing them on the ends of a continuum. In either case, one mode emphasizes the need to make quick decisions through categorical information, whereas the other underscores the need to be accurate through effortful use of individuating information. The perceiver who must prioritize between these interaction goals is dubbed the motivated tactician. Using stereotypes can smooth interactions if both people agree on the stereotype or if the interaction is brief and inconsequential for the holder of the stereotype.

Because they are convenient, stereotypes often actively motivate perceivers to maintain them. Creating exceptional subtypes is one way to maintain an overall stereotype despite a few salient people who do not conform neatly to the group. Subtyping allows the perceiver to cognitively isolate people who are stereotype-inconsistent by explaining that while they belong to the stereotyped group, they do not entirely represent the group.

At the societal level, system justification theory argues that people stereotype to maintain the status quo, even at the expense of one’s own group. Some researchers argue that minority groups’ own negative stereotypes demonstrate the system-justifying effects of stereotypes. Some researchers also suggest that complementary stereotypes (e.g., poor but happy, rich but miserable) increase support for the status quo because they satisfy people’s desire to perceive their world as fair and legitimate.
MEASUREMENT: THE EXPLICIT AND THE IMPLICIT

Although stereotypes may reflect a cultural belief, the individual with that knowledge does not necessarily endorse such a belief, as argued by the dissociation model of stereotypes. Nevertheless, regardless of one's explicit prejudice level, a person may be primed to think of groups stereotypically. For example, the presentation of a group label facilitates the activation of subsequent stereotype-consistent associations for both low- and high-prejudiced people. Implicit stereotypes can persist, even when explicit stereotypes do not.

Incongruent results from explicit and implicit stereotype measures illustrate the dissociation between personal endorsement and cultural knowledge. They also demonstrate that perceivers are often unaware of their own cognitive associations, particularly if they are automatic. In addition, when egalitarian cultural norms discourage unfavorable prejudices of others, and perceivers have a self-interest to refrain from these expressions, implicit measures can extract more information than can explicit measures. In short, implicit measures may detect what remains elusive from explicit measures. Regardless of whether a measure is explicit or implicit, stereotype measures reveal biases toward stereotype-consistent information.

Explicit measures are straightforward. As with other attitude measures, researchers can assess stereotypes through self-reports of impressions about target groups. For example, perceivers can express their impressions of immigrants in their own words, which the researchers then code into manageable categories. Stereotypes might include immigrant groups’ traits, behaviors, socioeconomic status, and life satisfaction, for example. Alternatively, perceivers can rate on a scale of how characteristically immigrants are hard-working, engage in criminal behaviors, experience poverty, feel welcome in the host nation, and so on.

Implicit measures reveal attention, attribution, and memory biases toward stereotype-consistent information. People prefer to confirm their stereotypes, at an immediate perceptual level, detecting stereotype-consistent information more easily. Although they then attend to stereotype-inconsistent information, if present, they tend to explain it away: The out-group’s success was a fluke, the successful out-group individual is not typical, and so on. In general, an out-group’s stereotype-consistent behavior elicits internal attributions to the group’s enduring dispositions; stereotype-inconsistent behavior elicits external attributions to chance or temporary circumstances. If a particular negative trait stereotype affects a target group, that group’s failures could be attributed to the supposed negative trait. If an out-group member does behave negatively and stereotypically (e.g., the criminal activity of a black person), situational factors will likely be disregarded in explaining that person’s behavior. People also better recall and recognize stereotype-consistent information than stereotype-inconsistent information if they are busy and operating in the complex environments typical of everyday interactions.

Researchers also devise priming methods to study automatic stereotypic associations. Some involve subliminal presentation of priming stimuli. Study participants then perform various tasks—including word searches, lexical decision tasks, fluency-manipulated tasks, and interpretations of ambiguous behaviors—in which they might produce responses that indicate stereotypic associations to the primes. Reaction speed, performance quality, and stereotypicality of responses indicate level of stereotype activation. Compared to this preconscious (subliminal) presentation of stimuli, other priming manipulations explicitly present stimuli; thus the perceiver postconsciously produces the activated associations. The implicit association test consciously primes two categories and then measures differential reaction times to concepts that are stereotype-consistent to one of the primes but not the other. People often react more quickly to negative words following out-group primes and to positive words following in-group primes. Also using postconscious priming, neuroimaging studies show increased amygdala (vigilance) activation to images of out-groups. Automatic associations escape a person’s conscious awareness, but implicit measures subtly detect what lurks beneath the surface.

CONSEQUENCES: THE GOOD, THE BAD, AND MORE BAD

Stereotypes might result from historical accidents, unduly generalize across people, and mostly derogate, yet they persist. Nevertheless, the costs of stereotyping have more extensive effects, especially for the target. First, the perceiver glosses over individuating information about a target (preference for stereotype-consistent information foregoes potential knowledge gain). On their side, targets are evaluated at the category level and not according to individual characteristics. They might even be classified with others in a group with which they do not identify.

Inaccuracies of three types plague stereotypes. Stereotypic inaccuracy refers to the overestimation of the target group’s stereotypicality or the underweighing of its stereotype-inconsistent qualities. Valence inaccuracy entails exaggeration of the negativity or positivity of the group’s stereotypes. Dispersion inaccuracy results from over- or undergeneralizing the variability between group members. Nonetheless, some other researchers argue for studying the accuracies contained within stereotypes because in this view they reflect reality.
The effects of stereotyping increase concomitantly with prejudice. Stereotypes along with prejudice strongly predict discrimination, so prejudiced perceivers are much more likely to act on their prejudice to negatively stereotyped groups.

Stereotypes reach beyond themselves. Stereotype threat describes targets’ awareness of their group’s negative stereotypes in a particular and consequential performance domain; they can ironically perform worse than those who do not care about that domain. Furthermore, stereotype threat leads to the targets fulfilling the stereotype that haunted them in the first place. Some examples are black students in an academic setting and women in mathematical tasks, for whom performance was labeled as diagnostic of their ability. Stereotype-threat effects differ from self-fulfilling prophecies because they affect people without encountering a prejudiced person.

Self-fulfilling prophecies, also called behavioral confirmation, perpetuate stereotypes through the perceiver’s expectancies of confirmation and the target’s behavioral confirmations of the expectancy. For the perceiver, one utility of stereotypes is in making the cognitive and social load more manageable. Stereotypes may also be useful for targets who want to fulfill their interaction partner’s expectancies so that they can avoid conflict or focus on an aspect of the interaction they deem more important. The process, however, perpetuates stereotypes in society.

**STERILE CLASS**

**SEE** Physiocracy.

**STERILIZATION, ECONOMIC**

The term sterilization is used in international economics and macroeconomics to describe the actions a central bank undertakes in order to neutralize the effects of central bank interventions in the foreign exchange market on the supply of domestic currency in the economy. Sterilization usually takes the form of an open market operation, in which a central bank sells or purchases government bonds on an open market in the amount it purchases or sells foreign currency on the foreign exchange market, so that the amount of domestic currency in circulation remains unchanged.

Suppose for example that it takes $1.35 to purchase €1; that is, it takes 1.35 American dollars to purchase 1 euro (the currency of the European Union). Suppose further that the Federal Reserve System (the United States' central bank) wishes to keep the exchange rate from rising from its current level to say $1.50 for €1. To accomplish this task the American central bank must sell euros (foreign exchange) out of its reserves. Since the euros will be purchased with dollars, the supply of dollars in circulation will decrease and the supply of euros in circulation will increase. Thus the value of the euro will not rise relative to the dollar. But this action reduces the amount of domestic currency in circulation in the United States, which might not be desirable. For example interest rates might rise. In order to counteract this effect, the central bank may simultaneously purchase domestic (American) bonds in order to put domestic currency back in circulation. Similarly if a central bank is buying foreign currency to keep the value of domestic currency low, it can sterilize such intervention by selling bonds and removing from circulation domestic currency that was introduced by such foreign exchange market intervention.

If an intervention in a foreign exchange market is accompanied by a sterilization operation, it is called a ster-
Sterilization, Human

Ilized intervention. International economics theory states that a sterilized intervention has occurred when: (1) international assets are perfect substitutes; (2) there is full capital mobility; and (3) the uncovered interest parity holds (that is, if one tries to make money by borrowing at a low interest rate in one currency and investing at a high interest rate in another currency, any gains will be offset by the change in the exchange rate). However if international assets are not perfect substitutes, or there are barriers to the flows of capital across borders, sterilized intervention can be effective in maintaining a certain level of exchange rate while minimizing the effect of interventions on the supply of domestic currency. In his 2003 article “Is Official Foreign Exchange Intervention Effective?” Michael Hutchison argued that in practice sterilized interventions have been effective.

One recent example of a central bank actively engaged in sterilized interventions is the People's Bank of China, China's central bank. In order to prevent the value of RMB, Chinese currency, from rising too fast against the U.S. dollar in the early 2000s, the People's Bank of China was actively purchasing dollars while at the same time issuing its own central bank bills. As a result the effect of foreign exchange interventions on the supply of domestic currency was neutralized, and the People's Bank of China accumulated foreign reserves, while Chinese commercial banks accumulated their holdings of central bank bills, claims on the People's Bank of China. The reason sterilized interventions were effective in China is limited capital mobility in and out of China, as a result of which Chinese and foreign assets are not perfectly substitutable.

Less frequently the term sterilization is used to describe the actions a central bank might take in order to reduce the effects of international capital inflows on the supply of domestic currency in the country. This type of sterilization was important during the lending boom of the 1990s when many emerging markets experienced a surge in international capital inflows, which was accompanied by the rise in domestic money supply and therefore inflation. In his 1997 article “Sterilizing Capital Flows” Jang-Yung Lee provided a detailed discussion of the sterilization of international capital inflows.

STERILIZATION, HUMAN

Sexual sterilization can be effected through various surgical operations designed to prevent a person from reproducing. In its most radical form, sterilization involves castration, which is the removal of the testes (male) or ovaries (female) and the consequent destruction of the capacity to produce human germ cells (sperm or ova). Late in the nineteenth century advances in surgical technique provided alternatives to castration as the sole means of sterilizing humans. These new operations were simpler for surgeons to perform, were less dangerous for patients to endure, and had a much more limited impact on health.

In the 1880s the Scottish surgeon Lawson Tait initiated the operation of salpingectomy for women. Tait’s technique was introduced as a therapy for ectopic pregnancy, a potentially fatal condition that sometimes occurs when a fertilized ovum lodges unexpectedly in a fallopian tube. Removal of a section of each fallopian tube prevents any ovum from traveling to the uterus (womb), hence ruling out any future pregnancy.

Soon after Tait introduced salpingectomy, the Chicago surgeon Albert Ochsner developed the operation of vasectomy as a treatment for problems of the male prostate gland. Ochsner described how he removed a portion of the cord known as the vas deferens, removing the route a sperm travels. He endorsed vasectomy as a surgical option that would avoid objections raised against castration. Ochsner’s surgery was also innovative because he specifically prescribed it as a means of preventing convicted criminals from having children. Soon the operation was being recommended as a way to prevent parenthood among chronic alcoholics, sex criminals, the mentally impaired, and the poor.

Ochsner’s technique became popularized just as the eugenics movement began to take root in the United States. The term eugenics was coined by the English scientist Francis Galton in 1883. Galton believed that most human characteristics, from physical and mental traits to moral predispositions, were inherited. Eugenics was his name for the science that aimed to increase the number of “well-born”—healthy and productive people—in future generations. Many of Galton’s followers believed, as he did, that societies should eliminate the future births of...
In the last decade of the nineteenth century, the state of Michigan debated the adoption of a law to mandate “asexualization” (castration) of some repeat criminals as well as inmates of asylums and homes for the mentally impaired to prevent the birth of children with similar disorders. That law and similar efforts in Kansas and Pennsylvania were rejected between 1897 and 1905.

Two years later the Indiana prison doctor Harry C. Sharp, working in collaboration with J. N. Hurty, secretary of the Indiana Board of Health, convinced their state legislature to adopt what became the first involuntary sterilization law in the world. Sharp had introduced vasectomy into his practice at the Indiana Reformatory as a therapy to cure male inmates of onanism or habitual masturbation. After several hundred experimental surgeries, Sharp convinced legislators that the procedure was also valuable as an efficient means to prevent the reproduction by hereditarily diseased parents of criminals and similarly “defective” children. Following Indiana’s lead, by 1926 twenty-one other states had passed laws that allowed governmental boards, commissions, or officials of state prisons, asylums, or other institutions to choose people who would be sterilized.

In 1927 the practice of salpingectomy for “eugenic” purposes was endorsed by the U.S. Supreme Court in the case of Buck v. Bell. The lawsuit pitted the Virginia teenager Carrie Buck against the state doctor who directed the Virginia Colony for Epileptics and Feebleminded. Buck was sent to the colony because she was an unmarried mother—a “moral degenerate”—whose condition was supposedly inherited from her mother, Emma Buck, already a colony inmate. Testimony in the case suggested that Carrie Buck’s seven-month-old baby was abnormal as well, prompting an opinion for the Supreme Court by Justice Oliver Wendell Holmes Jr. that upheld the Virginia sterilization law, concluding: “Three generations of imbeciles are enough.” Later research disclosed that Carrie Buck had no hereditary “defects,” and her daughter Vivian eventually earned a spot on her grade-school honor roll.

With the Buck decision as precedent, ten more American states passed eugenic sterilization laws by 1937. More than 60,000 surgeries were performed in the United States under the authority of eugenics laws between 1907 and the late 1970s. Ten other laws sanctioning involuntary sterilization were enacted in countries in the Americas, Europe, and Asia. The most notable was the 1933 German law that was applied to almost 400,000 people in less than ten years.

In 1942 the U.S. Supreme Court revisited the issue of coercive sterilization, striking down an Oklahoma law that authorized surgery on habitual criminals. Jack Skinner, the prisoner who challenged the law, had convictions for armed robbery and chicken theft. He argued that no scientific evidence proved the trait of “criminality” to be an inherited characteristic. The Court overturned the sterilization law, calling it a violation of the Constitution’s equal protection clause because it applied to common crimes like Skinner’s chicken theft but provided an exception for tax evasion, embezzlement, or political graft. At the same time the Court did not disturb the Buck ruling, which stood as continued justification of operations on the disabled.

Other operations, often targeting ethnic or racial minority populations, occurred without legal sanction. Jews and the Sinti and Roma (“Gypsies”) were sterilized using X-rays or caustic chemicals as part of the Nazi death camp program of “research” during World War II (1939–1945). From the mid-1950s until the 1970s, reports surfaced of widespread sterilization of Latinas, African Americans, and American Indians in several states. In the wake of these revelations, most American laws with “eugenic” language were repealed in the 1970s. Several European countries instituted programs of restitution for victims of sterilization policies; the Canadian provinces of Alberta and British Columbia later paid reparations following lawsuits. In the United States, the Virginia General Assembly, which in 1924 had enacted the law used to sterilize Carrie Buck, became in 2001 the first state legislature to condemn the sterilization law it had passed in the name of eugenics. Apologies followed in Oregon, North and South Carolina, and California, the state where more than one-third of all U.S. sterilizations took place. In 2007, to mark the centennial of U.S. sterilization laws, both the first state to pass such a law (Indiana, 1907) and the last state (Georgia, 1937) repudiated their earlier sterilization laws. Reports of sterilization abuse focused on minority populations in Peru, the Czech Republic, and Brazil have continued to appear in the first decade of the twenty-first century.

Steroids

The generic term steroids refers to a group of substances sharing a common basic chemical structure, many of which function as hormones in the human body. The two best-known classes of human steroid hormones are corticosteroids and anabolic-androgenic steroids. Corticosteroids are hormones secreted by the adrenal gland, such as cortisol, which modulate a range of physiologic functions, such as inflammatory responses and blood pressure. Many synthetic corticosteroids have been developed, such as hydrocortisone, beclomethasone, and dexamethasone; these synthetic substances have effects similar to those of naturally occurring corticosteroids and are widely prescribed in medicine for a range of conditions. For example, hydrocortisone is often a component of skin creams used to treat poison ivy reactions or other inflammatory skin conditions; beclomethasone is a common component of inhalers used in the treatment of asthma; and high doses of corticosteroids are administered to recipients of organ transplants to prevent rejection of the foreign tissue. In low dosages, corticosteroids have few psychiatric effects, but higher doses may sometimes cause manic symptoms (e.g., euphoria, hyperactivity, increased self-confidence, and impaired judgment) or even psychotic symptoms (e.g., delusions or hallucinations) in some predisposed individuals. Corticosteroids have very little potential for abuse and are rarely ingested by illicit substance abusers.

Anabolic-androgenic steroids represent an entirely different class of hormones. The prototype hormone of this class is the male hormone testosterone, which is secreted primarily by the testes in males. Anabolic-androgenic steroids produce masculinizing (androgenic) effects—such as beard growth, male pattern baldness, and male sexual characteristics—together with muscle-building (anabolic) effects. These latter effects account for the greater muscle mass and lower body fat of men as compared to women. Many synthetic anabolic-androgenic steroids have been developed over the last fifty years. Like testosterone, these synthetic substances produce both anabolic and androgenic effects; there are no purely anabolic or purely androgenic compounds. In medical practice, the principal use of testosterone is in the treatment of hypogonadal men—men who do not secrete sufficient testosterone in their own bodies, and who therefore require testosterone supplementation to maintain normal masculine characteristics. Aside from this application, anabolic-androgenic steroids have only very limited medical uses, such as in the treatment of certain forms of anemia

Unlike corticosteroids, anabolic-androgenic steroids are widely abused by individuals wishing to gain muscle and lose body fat. The great majority of these illicit users are male; women generally do not abuse anabolic-androgenic steroids because of the drugs’ undesirable masculinizing characteristics, such as beard growth, deepening of the voice, and shrinkage of the breasts. Men generally do not have to worry about these masculinizing effects and therefore may take doses far in excess of the amounts naturally present in the body. Specifically, an average man secretes between 50 and 75 milligrams of testosterone per week in his testes, whereas illicit anabolic-androgenic steroid abusers often ingest the equivalent of 500 to 1,000 milligrams of testosterone per week. When taken in these very high doses, anabolic-androgenic steroids can produce dramatic increases in muscle mass and strength, making it possible for users to far exceed the upper limits of masculinity attainable under natural conditions, without these drugs. Because of these properties, anabolic-androgenic steroids are widely used by athletes in sports requiring strength or muscle mass for feats such as hitting home runs in baseball or playing line positions in American football. In the United States there have been many recent well-publicized cases of prominent professional athletes who were found to be taking anabolic-androgenic steroids, and this issue became a subject of several congressional hearings in 2005. In addition, anabolic-androgenic steroids are increasingly abused by boys and young men who have no particular athletic aspirations, but who simply want to look more muscular. This pattern of abuse is particularly prevalent in North America, Australia, and some European countries—cultures where masculinity is sometimes portrayed as a measure of masculinity. By contrast, anabolic-androgenic steroids are rarely abused for purposes of body image in Asia, probably because Asian cultural traditions do not emphasize masculinity as an index of masculinity. However, anabolic-androgenic steroids are certainly used by some Asian athletes, especially at the elite level because these individuals are seeking a performance advantage, rather than a body-image effect.

In Europe and North America illicit anabolic-androgenic steroid use represents a significant and probably
growing public health problem. Taken in massive doses, these hormones may pose long-term medical risks, especially because of their adverse effects on cholesterol levels, which may greatly increase the risk of heart attacks or strokes at an early age (sometimes in the forties or fifties). In addition, high doses of anabolic-androgenic steroids may have psychiatric effects such as irritability, aggressiveness, and even violent behavior (sometimes popularly called “roid rage”) in some individuals. Thus, these drugs may pose a danger not only to users themselves, but even to some nonusers—particularly women—who may become victims of such violence. Men who use anabolic-androgenic steroids for long periods may also suffer depressive symptoms, sometimes accompanied by suicidal thoughts or even successful suicide, if they abruptly stop these drugs. Despite these risks, however, it appears unlikely that illicit anabolic-androgenic steroid use will decline in the near future because these drugs are readily available on the black market and offer a great temptation to men seeking muscle and strength gains.

STICKY PRICES

Price stickiness, the failure of prices to adjust fully in the face of evolving equilibrium conditions, reflects a lack of responsiveness to changes in supply and demand. This phenomenon has received considerable empirical and theoretical attention. To begin with, Barro and Grossman (1980), an early New Keynesian exposition on general disequilibrium, establishes the potential macroeconomic implications of such stickiness as divergence from equilibrium in the form of price rigidity in one market spilling over to others. For instance, they demonstrate how excess demand or supply in labor or commodity markets can stimulate more general macroeconomic shifts.

Approaching the question from a slightly different perspective, John Taylor (1980) adopts a rational expectations framework with staggered wage contracts (the sole source of wage rigidities in his model) to explain the persistent unemployment observed during postwar business cycles.

While Barro and Grossman (1980), Taylor (1980), and related work generally takes for granted price stickiness (typically by assuming some mechanism for it), to explore its larger macroeconomic implications, most theoretical work has been concerned with finding plausible microeconomic foundations for the emergence of price rigidities. These efforts have generated two principal veins of inquiry: one focused on price stickiness as a possible consequence of government intervention and the other on rigidities introduced by contractual commitments set by optimizing agents.

Several avenues of state intervention have received theoretical attention. First, governments frequently regulate the prices of various goods and services. To be meaningful (i.e., consequential), these restrictions must be binding in the sense that the resulting price in the market differs from what might otherwise have emerged under ordinary equilibrium circumstances. For instance, a legally mandated minimum wage (a kind of price floor) would influence prevailing wages only in sectors of the labor market where the equilibrium wage is below that mandated minimum. Such regulations undermine the full impact of many potential shifts in supply and demand, as changes in equilibrium price that would be evident in the absence of them are no longer so in their presence. Another important form of government interference with market prices comes in the form of attempts to fix (or peg) exchange rates. This has given rise to a literature (e.g., Krugman 1979, who builds on the work of Salant and Henderson 1978) focusing on the idea that such policies drive a wedge between the prevailing exchange rate (which is determined by the government’s peg) and the “fundamental” exchange rate (that which would prevail in an unfettered foreign exchange market). If the two diverge sufficiently, the government’s ability to defend the fixed rate may be overwhelmed by speculative pressure.

On balance, however, more theoretical attention has been directed toward the possibility that stickiness might arise as a result of contract setting (the consequences of which in terms of price rigidities are straightforward) and other purposeful behavior by optimizing agents. For instance, “menu costs” have received a great deal of attention (see, for instance, Mankiw [1985] for a thorough review of menu costs). Essentially, this approach is rooted in the idea that prices might not respond to shifts in supply and demand if the transaction costs (in a variety of senses) associated with adjusting prices are sufficiently
high. At the most trivial level there is a cost associated with adjusting menus and price labels. For instance, in markets characterized by monopoly or oligopoly, shifts in demand might yield changes in the prevailing market price only if the transaction costs associated with adjusting price are less than the erosion of profits that would occur if firms simply maintained their prices. On a more subtle level, frequent adjustment in prices might undermine consumer confidence or trust (e.g., if they believe that the frequent price changes represent some effort at manipulation).

Another popular line of inquiry revolves around “efficiency wages” (see Akerlof and Yellen 1986), which are set above the labor market equilibrium with the intention of promoting higher worker productivity. Frequently cited justifications for paying efficiency wages include discouraging shirking (because the financial penalty associated with being fired is greater), avoiding adverse selection (since workers with higher capabilities may be more inclined to apply for jobs with a higher wage), and reducing turnover costs (as individuals may be reluctant to quit a job with a higher-than-market wage).

A large body of empirical work is concerned with price stickiness. The principal objectives of this literature are to determine whether price stickiness actually arises in practice and whether the various theoretical explanations of price stickiness are consistent with observed empirical patterns. Rotemberg (1982) is one among many reporting evidence of price stickiness. Using U.S. data, he finds that it arises because of the transaction costs that firms incur when they change prices.

Despite the extensive empirical and theoretical literature concerned with it, the concept of price stickiness has met with skepticism. Lucas and Sargent (1978) and other New Classical economists challenge the idea that prices (or wages) are slow to adjust, suggesting instead that rational agents formulate price expectations using all available information in such a fashion that prices and wages should quickly readjust to equilibrate the market.

STIGLER, GEORGE JOSEPH
1911–1991

The years following World War II (1939–1945) saw a generation of remarkable economists who managed among themselves to remake the economics discipline and profession. Of this group, perhaps none possessed a better economic intuition or a keener economic mind than George Stigler. Though not as much of a public figure as his close colleague and longtime friend, Milton Friedman (1912–2006), Stigler did as much, if not more, to form what became known as the Chicago school of economics. It was at Chicago that Stigler would conduct research that not only gained him a Nobel Prize in 1982 but also ultimately changed the course of economic analysis. He had a rare talent for asking the right questions and putting forth provisional answers that inevitably provoked the profession and caused it to reconsider commonly held truths. At the same time, no economist was more a reflection of the ideological struggles of postwar America than Stigler.

George Joseph Stigler was born in Renton, Washington, on January 17, 1911, to immigrant parents. His choice to attend the graduate program at the University of Chicago in 1933 was perhaps his most fateful decision. It was there that he formed a lasting friendship with Friedman as well as becoming acquainted with Aaron Director (1901–2004), a young lecturer in the Department of Economics. These two would be among
the very few who ever managed to significantly influence Stigler's thinking.

Despite his early and continuing contributions in the field of the history of economic thought, his lasting contributions were in industrial organization and government regulation, two fields he essentially helped form. It is perhaps easiest to understand Stigler's lifework by grasping its essential consistency. In some sense he was a self-appointed white knight dedicated to defending the innocent damsel of traditional price theory against all and any attacks. He developed a knack for demonstrating the efficiency of markets despite and against all appearances to the contrary.

His pioneering work in industrial organization reinforced the core idea that markets work. Two noted works make this amply clear. “The Economics of Information” (1961) analyzes how markets use available information in the most efficient way. His “Theory of Oligopoly” (1964) essentially concludes that the traditional theories of perfect competition and monopoly could amply handle any issue dealing with market structure. (He would later push this further and eliminate the need for monopoly theory as well, indicating that competitive markets were sufficient to encompass the needs of economic analysis.)

If the first part of his postwar research helped to define the field of industrial organization by emphasizing the efficiency of markets, the second half demonstrated the inability of governments to improve outcomes through regulation. “What Can Regulators Regulate? The Case of Electricity” (1962), jointly written with his longtime associate Claire Friedland, empirically indicated that government regulation of public utilities made no real difference in cost. What were then unexpected results helped to precipitate research that ultimately led to the deregulatory movement in public policy. In the same way, Stigler’s analysis of the political market for government regulation, “The Theory of Economic Regulation” (1971), led to new research exploring how politicians operated and how and why government regulation became law. By ascribing narrow self-interest as the motivation for politicians, Stigler made a major contribution to the expanding field of public choice.

His final work on the role of government, exemplified by the posthumously published “Law or Economics,” is perhaps his most controversial. Logically, political markets should resemble economic ones in that they are both under the sway of the time. If an existing arrangement is not the most efficient one, then this should create a situation in which economic agents could benefit through improving the status quo. Therefore whatever is, must by definition be efficient. Otherwise it would change. Such an approach follows perfectly from Stigler’s lifetime drive to become increasingly more consistent in his analysis. At the end of his career, he surveyed an economic world where competitive markets ruled and provided the only useful analytical key.

Unlike Friedman, his close friend, Stigler deliberately eschewed a public presence. Yet without Stigler providing micro-based research, Friedman and his counterrevolution against the forces of Keynesianism and other non-mainstream approaches would have failed to achieve its singular success. Stigler remained active and at his beloved University of Chicago from 1958 until his untimely death on December 1, 1991. He was a scholar of great but cutting wit who had a talent for forming either fierce friendships or lasting animosities. Anything lacking intensity was never his style.

PRIMARY WORKS

Craig Freedman

STIGLITZ, JOSEPH E.

1943–

Joseph E. Stiglitz, born in Gary, Indiana, received his PhD from the Massachusetts Institute of Technology in 1967. A winner of the John Bates Clark Award for young economists, he has taught at Yale, Princeton, Stanford, MIT, Oxford, and Columbia University. In 1986 he founded the Journal of Economic Perspectives. In 2001 he was awarded the Nobel Prize in economics.

Stiglitz’s initial academic output, including his first two published articles in 1967, focused on how economic growth is affected by investment, risk, and income and wealth levels. In the early 1970s he and Michael Rothschild developed important insights into the nature of risk in financial and insurance markets. By the mid-1970s he was exploring problems of exhaustible natural
resources, sharecropping, efficiency wages, and discrimination, even while looking more deeply into the nature of information and risk in insurance and financial markets.

Working simultaneously on theoretical problems and on applied issues led Stiglitz to his breakthrough insight regarding the importance for economics of imperfect information, a term Stiglitz first used in two 1976 papers. As discussed by Stiglitz and Andrew Weiss in their 1981 article, this notion, sometimes denoted asymmetric information, refers to situations in which some participants in a market know more than others and can use their informational advantage to affect the efficiency of market outcomes. This informational advantage is often held by “agents” who hope to contract with “principals” controlling scarce resources—for example, applicants seeking jobs from potential employers and prospective borrowers seeking credit from lenders. Principals can then often best achieve their goals by supplying fewer loans (or fewer jobs) than are demanded. As Stiglitz argued in his 1987 article, prices are not in these cases permitted to rise to levels at which demand equals supply; indeed, in these models the quality of the commodity traded (the productivity of workers or default level of borrowers) depends on price. Their profits are often largest at a “rationing equilibrium”—a price wherein the quantity that agents seek to buy (or sell) exceeds the quantity that the principal supplies (or buys). At rationing equilibria, market forces will generally not equalize supply and demand.

These insights generated what Stiglitz calls the economics of information, which explores the consequences of information asymmetries in credit, financial, product, and labor market. New information-based paradigms have been developed in development economics, trade theory, and other fields; and information-based models have been central to the emergence of the microfoundational “New Keynesian” (named for the preeminent economist John Maynard Keynes) approach to macroeconomics.

The economics of information suggests that selective government interventions and/or nonmarket institutions can enhance growth and reduce poverty. Stiglitz became increasingly involved in the policy implications of these ideas, triggered by an extended period in public service. He served on the Clinton administration’s Council of Economic Advisers from 1993 to 1997, the last two years as chair. He then became chief economist and senior vice-president of the World Bank from 1997 to 2000. While at the World Bank, he publicly challenged the so-called Washington Consensus, that is, the then-prevailing practice at the World Bank and International Monetary Fund of using full-information, competitive-economy models to understand global and developing-country economic outcomes. In Stiglitz’s view, more realistic models would show that global economic forces have often jeopardized viable local governmental and institutional economic arrangements. Amid considerable controversy, as Ha-Joon Chang notes in his 2001 book, the World Bank made some changes in its modeling and policy approaches. Stiglitz tells his side of the story in his bestselling 2002 book, Globalization and Its Discontents.

Two articles summarizing Stiglitz’s work in light of his Nobel prize are Chang’s (2002) and J. Barkley Rosser’s (2003); Stiglitz’s own summary of his ideas and their implications for the change in the economics paradigm appears in his 2003 and 2004 articles.

STIGMA
Although the term originally described a mark made through branding to designate a person of undesirable moral character, stigma was introduced into the psychological literature by Erving Goffman in 1963 to refer more broadly to any attribute or characteristic that makes its
bearer tainted or devalued by others. Jennifer Crocker, Brenda Major, and Claude M. Steele (1998) refined the definition, noting that stigmatized characteristics convey “a social identity that is devalued in a particular social context” (p. 505). This definition highlights two important properties of stigma. The first is that the stigmatized characteristic is attributed meaning beyond the characteristic itself—it is often assumed to be broadly reflective of the person or his or her identity. The second property is that personal characteristics lead to stigma through their context-specific symbolic value, rather than through inherent properties of their own. Wrinkles and white hair, for example, may be revered as a sign of wisdom and experience when it comes to relationship advice, but may lead to undeserved assumptions of incompetence when it comes to navigating computers.

Goffman distinguished among three types of stigmas: tribal stigmas (e.g., racial, ethnic stigmas), blemishes of individual character (e.g., drug addict, criminal offender), and abominations of the body (e.g., weight, body scars). Despite enjoying wide recognition, Goffman’s typological approach has given way to a more dimensional approach to stigma, one relying more on general principles that help understand the underlying differences and commonalities among stigmas. In 1984 Edward E. Jones and colleagues proposed six such dimensions: degree of concealability, degree of change over time, degree of disruptiveness, how aesthetic others find the attribute, how the stigma originates, and degree of peril the stigma poses.

**IMPACT OF STIGMA ON ITS TARGETS**

The psychological impact of these dimensions, particularly concealability and responsibility, has been a topic of intense study. Research on the dimension of responsibility in particular has shed light on the internalization hypothesis—the notion that people internalize society’s negative ascriptions about their group, with negative consequences for their self-concept. Early studies included Kenneth B. and Mamie P. Clark’s 1947 doll study, which found that young African American children preferred to play with white dolls rather than black dolls. Although the children’s responses may have stemmed from their efforts to please the researchers or an unfamiliarity with black dolls, the findings were widely interpreted as evidence for the deleterious effects of stigma on the self-concept.

This interpretation remains popular despite empirical evidence to the contrary. Research consistently shows that the self-esteem of African Americans is, on average, higher than the self-esteem of U.S. whites. In 1989 Crocker and Major proposed that stigmatization may actually protect self-esteem, such that when people know they are the targets of stigma, negative outcomes can be attributed to the prejudice of others rather than to one’s talents or efforts (thereby protecting self-esteem). Nevertheless, attributions to prejudice are protective only to the extent that people believe that they are not to blame or that the prejudice is undeserved. For example, overweight women, when rejected on the basis of their weight, nevertheless show a drop in self-esteem, presumably because they endorse the notion that weight is controllable and a matter of willpower. Thus perceptions of responsibility/controllability may influence the impact of stigma on the self. A thus-far unresolved puzzle is whether and how stigma affects the self-esteem of Asian Americans, Latinos, and Native Americans in the United States, who show lower self-esteem than U.S. whites.

Importantly, one does not need to believe or internalize relevant stereotypes in order for them to have adverse consequences. This is evident from research on stereotype threat, which shows that performance (e.g., on tests) is affected following the mere awareness that one might be viewed or judged according to a stereotype. For example, whereas women underperform relative to men in a math task when reminded about gender differences, performance differences disappear when the same task is framed as gender-neutral—that is, when the threat is removed. These data, also replicated among stigmatized minorities in the academic domain, are powerful demonstrations against nativist views of performance differences. Subsequent research shows that the cognitive and emotional disruption of having to contend with stereotypes plays a critical role in explaining group-based performance differences where stereotypes are involved.

Individuals may use a variety of strategies to cope with the threat of stigmatization. Behaviorally, people may avoid situations or contexts in which a particular identity is devalued. Psychologically, individuals may disengage, and ultimately disidentify, from the domain in which their group is stigmatized. Proactive strategies may include efforts to disprove the stereotype, as well as social activism. Thus, people are not merely passive recipients of social judgments and evaluations, but rather they psychologically construe and physically shape their social worlds to actively cope with the problem of stigma.

**WHAT LEADS PEOPLE TO STIGMATIZE OTHERS?**

Approaches to stigmatization from the perceiver’s perspective have a longer history and fall into two broad approaches: motivational and cognitive. They both encompass stereotypes, prejudice, and discrimination, terms that roughly correspond respectively to beliefs, attitudes, and behavior. The cognitive approach conceptualizes stigmatization as a by-product of human information-processing biases. The basis for this approach is that people naturally
Stimulus, Unconditioned

use schemas, or mental categories, to reduce the potentially limitless number of stimuli in the world into more manageable groupings. Schemas provide not only an organizing principle to help individuals navigate the world, but also a way for people to “fill in the blanks” as needed: A person assumes a new chair will have the properties to support his or her weight, even though the person has never sat on it. According to the cognitive approach, similar processes apply when a person stigmatizes others: A person may assume, for example, that a new female acquaintance cannot read a map though the former has no experience or information on this woman’s map skills. Despite being unfair or even harmful to the perceived (by eliciting stereotype threat, for example), these cognitive processes perpetuate stigma because they confer to the perceiver the benefit of having to use relatively few mental resources. Further, some mental associations may be relatively automatic, that is, outside of awareness, so that even people who are motivated to be egalitarian and sincerely believe they are not prejudiced can stigmatize others unwittingly.

By contrast, the central idea behind the motivational approach is that people stigmatize others to feel better about themselves. Research shows that individuals receiving negative feedback about themselves are more likely to discriminate against stigmatizable others, and that this restores self-esteem. Existentiell oriented work proposes that people use symbolic means, including a deep investment in cultural or societal ideals, to transcend death. Thus, when reminded of their mortality, people are more likely to be less tolerant of others who subscribe to different worldviews (e.g., religion, political orientations). Newer views suggest that specific intergroup attitudes and behavior depend on the amount of intergroup competition as well as the group’s perceived status. A high-status group that one competes for resources with, for example, tends to be viewed as competent and cold, eliciting envy. By contrast, a low-status group that does not represent a competitive threat tends to be seen as incompetent and warm, eliciting pity. Thus the field is moving toward identifying specific emotions and attitudes associated with different manifestations of stigma. Together with an increasing volume of research identifying processes related to being the target of stigma, the field is moving toward an approach is that people stigmatize others to feel better about themselves. Research shows that individuals receiving negative feedback about themselves are more likely to discriminate against stigmatizable others, and that this restores self-esteem. Existentiell oriented work proposes that people use symbolic means, including a deep investment in cultural or societal ideals, to transcend death. Thus, when reminded of their mortality, people are more likely to be less tolerant of others who subscribe to different worldviews (e.g., religion, political orientations). Newer views suggest that specific intergroup attitudes and behavior depend on the amount of intergroup competition as well as the group’s perceived status. A high-status group that one competes for resources with, for example, tends to be viewed as competent and cold, eliciting envy. By contrast, a low-status group that does not represent a competitive threat tends to be seen as incompetent and warm, eliciting pity. Thus the field is moving toward identifying specific emotions and attitudes associated with different manifestations of stigma. Together with an increasing volume of research identifying processes related to being the target of stigma, the field is moving toward a more precise, balanced science.

STOCHASTIC FRONTIER ANALYSIS

Stochastic frontier analysis (SFA) refers to a body of statistical analysis techniques used to estimate production or cost functions in economics, while explicitly accounting for the existence of firm inefficiency. The operative word in this definition is inefficiency, which implies producers may behave suboptimally in their decisions to maximize or minimize some objective function (e.g., profits, production, revenue, or costs). The intellectual underpinnings of inefficiency in economics can be traced to the writings of John Hicks (1938), who argued that monopolists possess motivations other than those of pure profit maximization; these motivations may lead to suboptimal production. (See Kumbhakar and Lovell [2000] for other rationalizations for inefficiency in equilibrium and a discussion of its intellectual underpinnings.)

The empirical departure point for SFA is the production frontier model, originally formulated by Aigner,
Lovell, and Schmidt (1977) and Meeusen and van den Broeck (1977). Let
\begin{equation}
y_i = x_i' \beta + v_i - u_i, \quad i = 1, ..., N
\end{equation}
where firm \( i \) seeks to maximize production of observable output \( y_i \), employing linear production function \( x_i' \beta \). Observable production inputs (e.g., labor and capital) are in column vector \( x_i \) and marginal products are the corresponding column vector of unknown parameters, \( \beta \). The \( v_i \) is a zero-mean, symmetric error. The salient feature of the model is non-negative error, \( u_i \), representing unobserved inefficiency, so the specification is a leading case of an error-component model. The deterministic portion of the specification, \( x_i' \beta \), represents the frontier of maximal output for a given set of inputs \( x_i \). The symmetric error, \( v_i \), causes the frontier to be stochastic. The one-sided inefficiency term, \( u_i \), can only reduce output and represents departure from this frontier.

If the inputs and outputs are in natural logarithms, then equation 1 is a Cobb-Douglas production function. Other common functional forms, such as the translog, can be modeled with appropriate selection of the components of \( x_i \). For example, a cost frontier can also be estimated if \( y_i \) is total cost and \( x_i \) are total output and input prices. Depending on the specification, \( u_i \) can be technical (production), revenue, profit, or cost inefficiency.

Estimation of the parameters in equation 1 is complicated by the fact that the mean of inefficiency is nonzero but either a modified ordinary least squares or a maximum likelihood algorithm are typically employed. For this particular specification, identification is achieved from an independence assumption on \( x_i, v_i, \) and \( u_i \) by specific distributional assumptions on the error components, such as \( v_i \) normal and \( u_i \) truncated normal, exponential, or gamma (Greene 1990). These assumptions may be difficult to justify. In particular, it has been argued that inefficiency is correlated with input mix and that specific distributions for the errors are too restrictive. Schmidt and Sickles (1984) relax these assumptions by considering panel data (firms observed over multiple time periods) to fixed-effect estimation, where inefficiency is nonstochastic and time-invariant.

Methods for quantifying inefficiency itself are due to Jondrow et al. (1982), whereas Horrace and Schmidt (1996, 2000) develop methods from inference on inefficiency. Generalizations of the basic model are plentiful. Semi- and nonparametric estimation techniques have been considered (Fan, Li, and Weersink 1996). Time-varying inefficiency was first considered by Cornwell, Schmidt, and Sickles (1990) and Kumbhakar (1990). Applications are unlimited but include estimation of frontiers for industries in the manufacturing and services sectors, for government entities, and for samples of countries. There is also a complementary Bayesian estimation literature (van den Broeck et al. 1994). Finally, there is a competing, purely deterministic methodology called data envelopment analysis, or DEA, developed by Charnes, Cooper, and Rhodes (1978).

STOCK EXCHANGE
Stock exchanges are organized markets where investors buy and sell shares of corporate stock and bonds. Some of the better-known stock exchanges are the New York Stock Exchange (established in 1792), the Tokyo Stock Exchange (1878), and the London Stock Exchange (1698). Stock exchanges are important insofar as they promote economic efficiency. They offer private investment opportunities to individuals and direct a large part of production in capitalist societies. If stock exchanges work well, this efficiency will promote efficiency in the general economy.

Corporations promote economic efficiency by producing goods that consumers want most urgently and keeping production costs to a minimum. Investors speculate over which corporations will be most efficient and profitable before they buy corporate stocks. After buying shares of stock, investors must monitor the activities of corporate officers to see that their company is operating efficiently to earn the highest potential profit. Corporate officers can mismanage their businesses in several ways. First, they can form faulty business plans. Management can invest in producing products that consumers do not want or invest in a production plan that is excessively costly. Second, corporate officials can mismanage the execution of essentially sound business plans. Third, corporate officials can commit deliberate fraud or deception for personal gain. In any case, stockholders in a mismanaged corporation will lose money.

Competition in stock exchanges determines who plans much of production. When corporate executives plan and carry out efficient production, profits rise and the price of the corporation’s stock increases. When corporate executives form defective business strategies or mismanage the execution of sound strategies, stockholders have an interest in replacing them. If stockholders do not replace incompetent corporate executives, then the price of the stock will likely fall. That is, if stockholders do not deal with inefficient corporate executives, the stock exchange can penalize stockholders by cutting the value of their stock. This is how stock exchanges pressure corporate shareholders to terminate incompetent corporate managers. Of course, stockholders may not respond to such pressure from the stock market. However, if stockholders fail to remove incompetent corporate managers, the low price of that corporation’s stock will make it an easy target for a takeover bid or leveraged buyout. In other words, a new group of investors could move to buy out some or all of the old stockholders and replace the existing management. Takeovers and leveraged buyouts often transfer ownership of a corporation from a large number of inattentive stockholders to a small number of large investors, who demand better performance from their executives. One of the more famous examples of such a move is when Henry Kravis bought out RJR Nabisco for $25 billion in 1989 and ejected CEO Ross Johnson.

Investors compete in stock exchanges to earn money for themselves. Yet competition between investors promotes the careers of efficient corporate executives and ruins the careers of incompetent ones. This is how stock exchanges determine who plans production. Of course, it always takes some time for pressure from the stock exchange to remove inept management from any particular corporation. However, stock exchanges do not tolerate incompetence indefinitely.

There are reasons to question the efficiency of stock exchanges. The key issue in stock exchange efficiency is information. A stock exchange is efficient if the price of each stock reflects all relevant and available information on that stock. Any stock that is undervalued, given available information, will be coveted—and its price will rise. Any stock that is overvalued will be sold off and its price will fall. In theory, such buying and selling of stocks will push stock prices to their true values.

Ideally, stock prices will reflect the actual performance of the corporate management. In actual stock exchanges, the price of corporate shares can overestimate or underestimate the performance of corporate management. Since investors have incomplete, and sometimes inaccurate, information regarding corporations, there will always be some inaccuracy in stock prices. Investors do, however, profit from being accurately informed, and this prompts them to eliminate serious deficiencies in their information. Stock prices move toward levels that reflect the true performance of corporate officers, but it always takes some time for pertinent information to be uncovered.

Efficient stock exchanges adjust to a continuous flow of new information, but the fact that this information is always incomplete means that stock prices are never perfectly accurate measures of executive performance. Trading with incomplete information is speculative, but unavoidable. The lack of perfect information means that stock exchanges can never achieve 100 percent efficiency, yet stock exchanges are relatively efficient if they adjust to new information as it becomes available. Some studies indicate that stock markets are efficient. Yet other studies
Stock exchanges indicate inefficiency. Stocks of small firms tend to earn excess returns in January, and returns tend to be low on Mondays. Also, upswings and crashes in aggregated stock prices (bull and bear markets) indicate that stock prices deviate from their true values, based on market fundamentals. For example, on October 19, 1987, the Dow Jones Index declined 22 percent. Some argue that this and other crashes are evidence of irrationality in stock exchanges, while others claim that the October 19 crash was triggered by the proposal by the House Ways and Means Committee to limit the deductibility of interest on corporate debt.

While it is obvious that stock exchanges are not perfect, the case for regulating stock exchanges is less clear. Some insist that anomalies in stock exchanges indicate a need for government regulation. Given the importance of stock exchanges in modern economies, governmental regulation that improves stock exchange performance can improve overall economic conditions. On the other hand, government regulation is sometimes flawed and will sometimes impair market performance. Expert opinion is divided over the issue of stock exchange regulation, but there is a considerable amount of evidence indicating that current regulations are excessive.

We can illustrate the importance of stock exchanges by examining the economic performance of countries where they do not exist. Stock exchanges are particular to capitalism. Socialist economies prohibit private ownership of stocks, private dividends, and stock exchanges. In a socialist society, all citizens have an equal stake in all parts of industry and all are paid a social dividend as equal owners of industry. Since socialist societies lack stock and other financial markets, socialist production gets directed by central authorities. This is a critical difference between socialism and capitalism. Twentieth-century experience with Soviet-style central planning indicates that Wall Street does a better job of directing industry than do central authorities. While there is room for doubt concerning the need for regulation of stock exchanges, there is far less doubt about the need for some kind of market for trading equities. Stock exchanges are an indispensable part of modern economies because they provide an efficient means of planning production in an efficient manner. Without stock exchanges, capital investment would be far less efficient.

Some recent proposals for socialism would allow people to own shares of stock in particular businesses. However, every citizen would be limited to an equal amount of stocks that could be traded only for other stocks. Advocates of this proposal believe that this sort of limited stock exchange would improve managerial performance, while approximating equal ownership of the means of production. However, a "socialist stock exchange" would not be as effective at removing inept managers, simply because it would eliminate hostile takeovers and leveraged buyouts at the hands of large professional investors.

Stock exchanges promote overall economic efficiency, despite the occasional appearance of significant flaws. Improvement in information technology has improved the efficiency of stock markets, and this trend will most likely continue. The general public often misunderstands the role that stock exchanges play in modern economies. People often see stock trading as a purely financial matter, but stock exchange activity is important for planning real production. Stock exchanges have and will continue to play a central role in modern economies because of their indispensable role in promoting economic efficiency.

**STOCK EXCHANGES IN DEVELOPING COUNTRIES**

Stock exchanges play an important role in developing countries. One of the major challenges that developing countries face is capital formation. In economic terms,
capital consists of equipment and machinery used to make consumer goods. The capital structure of developed nations consists of many different types of capital goods organized in factories and industries. Developed countries have capital goods arranged in stages of production. For example, iron ore is first mined, then it is refined, then it is made into steel. Steel is then shaped and assembled into final products, like cars and buildings. Workers use capital equipment at each stage to produce final goods for consumers.

Capital goods derive from financial investment. In order to develop a modern capital structure, someone must invest in buying capital goods. Stock exchanges provide a source of funding for capital investment. When a corporation forms or expands, it needs money to invest in capital (as well as labor and other supplies). The executives of the corporation can raise money for capital by selling new shares of stock in a stock exchange. Each share of stock entitles its owner to part of a corporation's future profits. Sales of new shares in stock exchanges serve two purposes. Stock exchanges enable individuals to invest their own money for private gain. Stock exchanges also enable businesses to raise money to buy capital equipment. This is important for many developing countries that lack advanced capital equipment. The alternative to development through private investment is government funding for investment projects. Government-funded investment projects can be financed either by a nation's own government or through direct foreign aid.

Stock trading also determines who runs corporations. If a corporation is run well, its stockholders will earn a high dividend or capital gains on the price of their stock. If corporate management runs a corporation badly, the price of the corporation's stock will fall. When a corporation's stock price falls dramatically, it is easy for new investors to buy up shares of the stock and replace the management. This is how stock exchanges get rid of incompetent corporate executives. Stock exchanges thus help developing countries to avoid waste from incompetent corporate management.

Stock exchanges played an important role in the development of industrial western Europe and North America. The London Stock Exchange emerged in the eighteenth century. Initially, brokers traded stocks in coffeehouses and private clubs. The stock market in Amsterdam emerged in the seventeenth century. The financial system of Belgium dates to at least the fourteenth century, but the Brussels Stock Exchange opened in 1801. Initially, these stock exchanges were informal and simple. With the passage of time, these early stock exchanges developed into sophisticated institutions with formal rules. Eventually, stock exchanges in major cities began to direct capital investment throughout the West and in parts of Asia. For example, Belgium developed rapidly during the nineteenth century. Statistical studies indicate that the economic development of Belgium was driven by the development of Belgian financial markets, including the Brussels Stock Exchange. Financial development in Belgium began with the country's independence in 1830, and was accelerated by the liberalization of the Belgian stock market in 1867. This pattern was paralleled in many nations. Statistical studies show that well-developed stock exchanges have enhanced long-run economic growth, increased capital investment, and raised productivity throughout the industrialized world.

Since the 1970s many developing nations have begun to form more advanced financial markets. One study (Agarwal 2001) of nine African nations indicates that stock exchange development has led to increased economic growth. Another study (Mohtadi and Agarwal 2007) of twenty-one developing nations shows that the development of stock exchanges increases private investment and economic growth. This study indicates that stock exchanges contribute to economic development by stabilizing productivity and liquidity shocks.

As stock exchanges develop, the issue of financial regulation arises. Some evidence supports the case for liberalization of stock exchanges. Peter Henry (2003) finds that deregulating stock exchanges reduces capital costs and increases investment and per worker productivity. Liberalized stock exchanges can also facilitate the adoption of new technologies in developing nations. Some distortions in the international financial system led investors to hold too much debt and too little equity (Henry 2006). The liberalization of stock exchanges has caused a shift from debt to equity holding during the 1990s. This shift from debt to equity caused a short run increase in economic growth. Henry (2000) also finds that liberalizing stock exchanges can reduce the cost of equity capital by allowing risk-sharing between foreign and domestic investors.

Some scholars point to examples of stock market crashes as evidence of need for regulation. The 1929 crash on Wall Street is well known, but there are more recent examples of stock exchange panics to examine. The Kuwaiti stock market crash of 1982 is often cited as an example of how stock markets need regulation. The Kuwaiti crash left investors with over $90 billion of debt and put serious strain on the Kuwaiti banking system. The Kuwaiti example indicates that stock exchanges can mal-function badly. It should be noted that the Kuwaiti crash represents only a single incident of stock exchange failure. While the Kuwaiti crash supports the case for stock exchange regulation, this incident does not prove the case for regulation.
Investment in stock exchanges typically leads to financial inequality as some investors earn fortunes, but stock exchange activity also promotes economic development and rising living standards for all. The inequality that arises from stock exchange activity may be an unavoidable part of economic progress. Stock exchanges appear to contribute to economic development in developing nations significantly. Regulation of emerging stock exchanges might yield some benefits, but there is a strong case for opening stock exchanges up to free competition and foreign investment.

STOCK OPTIONS

A stock option, also known as a derivative, is a contractual right, but not an obligation, to purchase (call) or sell (put) shares of a company’s stock at a future date and at a predetermined, or strike, price. A stock option fulfills two purposes simultaneously: It serves as a hedging instrument designed to reduce the financial risk of an investor holding a particular financial asset, and it serves as a speculative financial instrument by requiring a second investor to assume more risk in return for a potentially higher financial reward.

Employee stock options are call options and are not publicly traded. Employee stock options must be held by the employee for a specified period of time, termed the vesting period, before the option can be exercised. Employee stock options in the United States consist of two types: incentive stock options and nonqualified stock options. The difference between the two is that the profits from incentive stock options are taxed as a capital gain while those from nonqualified stock options are taxed as ordinary income.

Stock options have long been a component of corporate executive compensation packages. They have become increasingly popular over the past few decades as U.S. companies shifted away from accounted earnings to stock price as the primary measure of corporate performance. Granting stock options to corporate executives, it is argued, helps align their interests with those of shareholders by linking executive compensation to company stock price performance. In the 1990s employee stock options became more widely used in typical employee compensation packages for two reasons. First, unlike salaries,
Stockholm School

Employee stock options did not cost companies anything. Second, they were used to attract and retain motivated and entrepreneurial employees, especially in booming high-tech and cash-strapped start-up companies.

But employee stock options have been criticized for their potential to become worthless, or “underwater,” should the company stock price deteriorate. This was often the case after the dot-com crash in the late 1990s, which left many employees holding worthless stock options. Another criticism claims that the rules for reporting and accounting employee stock options are insufficient. This criticism arose after evidence surfaced that major corporations routinely backdated executive stock options in order to ensure higher financial rewards for those executives. Furthermore, there are criticisms of the Black-Scholes pricing model that is used in valuing stock options, and questions pertaining to whether employee stock options should be valued at the time they are granted or when they are exercised. These criticisms arose after the 2002 Sarbanes-Oxley Act strengthened compensation reporting and accounting measures and required companies to expense employee stock options. The act was a response to the wave of corporate scandals that surfaced in the United States between 1999 and 2001, in which corporate executives at such notable companies as Enron and WorldCom cashed in their stock options after artificially inflating their company’s stock price. Finally, employee stock options have been criticized as contributing to the increasing polarization of wealth, since the median total realized compensation (including gains from stock options) of the top Fortune 500 chief executive officers since the 1970s has nearly quadrupled while the real wages of workers has declined.

STOCKHOLM SCHOOL

The Stockholm School was a macroeconomic school that was parallel to but independent of the employment theory developed by John Maynard Keynes during the 1930s. It consisted of a number of Swedish economists who were all influenced by Knut Wicksell’s theory of the cumulative process of 1898. In Wicksell’s theory, increases in the price level are followed period by period, and inflation is assumed to be driven by the gap between the natural rate (profitability of investments) and the loan rate of interest. If the natural rate exceeds the loan rate of interest, investments and consequently demand for goods and labor will increase and so will the price level. This is in contrast to the quantity theory of money, which says that increases in the price level are caused by increases in the supply of money. Gunnar Myrdal’s analysis of expectations in his dissertation of 1927 forms a second influence on the Swedish economists.

The Stockholm School developed in three stages. In the first stage Myrdal and Erik Lindahl in the early 1930s discussed Wicksell’s criteria of monetary equilibrium (macroeconomic equilibrium), namely, that the natural rate of interest should equal the loan rate of interest, that saving should equal investments, and that the price level should be constant. One outcome of the discussion was that the second condition for monetary equilibrium should be formulated as equality between planned saving and planned investments—that is, ex ante, not between realized saving and investments, that is, ex post.

The second stage is connected with the unemployment commission of the Swedish government and the fact that Sweden during the 1930s was hit by the worldwide Great Depression. Myrdal (1934) wrote a report in which he discussed how fiscal policy (variations of government expenditure and of taxes) could be used to even out the business cycle. Bertil Ohlin (1934) discussed how monetary policy and custom duties could be used for the same purpose. The analyses of Myrdal and Ohlin are rather similar to that of Keynes in The General Theory of Employment, Interest and Money of 1936. For example, Ohlin’s contribution discusses multiplier effects of public expenditure (i.e., increased public expenditure may increase gross national product more than the original increase of expenditure).

The Swedish government took the advice of members of the Stockholm School, which some believe is the main reason Sweden was comparatively mildly affected by the Great Depression. However, the devaluation by 30 percent of the Swedish krona in 1931 probably had a much greater impact.

The third stage took place in the end of the 1930s when the analysis of the Stockholm School was refined. One example is Erik Lundberg’s dissertation from 1937; in anticipation of Paul Samuelson’s mathematical analysis of 1939, Lundberg demonstrated numerically that a combination of the acceleration principle (a theory that says that investments depend on the change of consumption) and the multiplier theory can be used to explain the business cycle.
The creative phase of the Stockholm School lasted to the end of the 1930s. After that only a few contributions were published. Like the Austrian business cycle theory of Mises and Hayek, the Stockholm School was surpassed by Keynesian economics. Whereas the Keynesian equilibrium theory was easy to use and to generalize, this was not the case for the Swedish analysis.

STOCKHOLM SYNDROME
SEE Traumatic Bonding.

STOCKS
Stocks are a type of financial instrument that represent ownership in a business organization. Ideally, the price of any stock is equal to the present value of expected future cash payments to the stockholder. Stocks perform specific and important functions in financial markets and in the economy generally. From the perspective of private investors stocks are a form of financial investment. Ownership of stock in a business entitles a person to part of the profits generated by the operation of that business. When a corporation realizes profits, it pays a dividend to its stockholders, though it will often retain some profits to finance additional business operations.

Stocks differ from other financial instruments mainly in terms of risk. For example, bond owners are paid interest according to their bond’s annual yield. Companies that issue bonds enter into a contract with bondholders to pay a specific amount of money over a specific time period. Once a bond matures, the company that issued the bond returns the money that it borrowed to the bondholders. Stockholders, in contrast, are the owners of that company. Since corporations are legally obligated to pay bondholders interest, bondholders risk default if the issuing company goes bankrupt. Since the dividend paid by the company varies with the performance of that company, stockholders can realize a poor rate of return without the company actually going bankrupt.

Economists view stocks as a particular type of institution that performs specific social functions. Stocks, and other financial instruments, play an important role in the functioning of capitalist societies. Stocks, bonds, and other types of loans are alternative means of financing the operations of a business. Stocks represent a means of raising financial capital for business investment. Anytime a business sells new shares of stock, the investors who buy them provide funding for new entrepreneurial business projects. Investors who buy new shares of stock in a company are speculating about the future profits of that company. If the projects that a company undertakes realize or exceed expected profits, its stockholders (unlike bondholders) will earn high dividends and capital gains. So the capitalists who buy shares of stock are speculators who attempt to predict future trends in the economy. Efficient businesses produce products that consumers want most urgently at a low cost. Efficient businesses will earn the most profits for their stockholders.

Capitalists who speculate accurately concerning different businesses can earn new fortunes for themselves by providing finance to efficient businesses. Capitalists who err in predicting future economic trends can lose previously accumulated fortunes. In this way stock ownership can work as a regulating mechanism to direct money into efficient businesses that need additional funding to expand and away from inefficient businesses whose operations should be curtailed.

Most stock trading involves previously owned shares of stock rather than newly issued shares. Trading of existing shares of stock is also important to the functioning of businesses. The price of existing shares of stock tells a company how much money it can raise by issuing new
shares. Of course, businesses need not use this method of finance, and many businesses buy up existing shares of stock to increase the value of the remaining shares. Yet stock ownership still affects the business's performance.

It is important to note that stock ownership implies a separation of ownership and control. Stockholders own a corporation, but the chief executive officer (CEO) or president actually manages the daily operations and plans the future operations of any corporation. Separation of ownership and control in a corporation, though, poses a potential problem. The CEO and other top executives may abuse their authority at the expense of stockholders. Both bondholders and stockholders have an interest in the efficient operation of the corporation in which they have invested. Under specific circumstances, bonds and stocks are virtually identical. If investors have perfect information on the activities of corporate officers, if taxes affect bonds and stocks equally, and if the costs of transacting for stocks and bonds are equal, then stocks and bonds will be perfect substitutes as far as investors are concerned. The logic behind this proposition is simple. If people have perfect information about the activities of corporate officers, then they will know exactly what the future stream of dividends will be. If a stock will pay more than a bond with certainty, then investors will buy more of that stock. When investors own more shares of a stock, its price will rise, and its dividend will fall. The rate of return of a stock will therefore be equal to the interest rate on bonds—if investors have perfect information on the operation of that corporation by its top executives. Investors might prefer stocks or bonds for tax reasons or because of differences in transactions costs. But given our three assumptions, bonds and stocks will appear identical to investors.

The idea that investors have perfect information is completely unrealistic, but it does tell us much about the real world. Stocks are different from bonds because of the differences in information needed to profit from these two types of investments. All bondholders need to know is that corporate officers are doing their jobs well enough so that the corporation can avoid bankruptcy and pay interest on its bonds. With stockholders things are different. Every penny that the corporate officers waste or take for themselves is money lost to the stockholders. Consequently, stockholders need to be much better informed about the activities of corporate officers than do bondholders. Bonds are a good investment for people who want a decent rate of return without much bother. Stocks can deliver a higher rate of return but require more attention from investors. Consequently, owners of stocks act as corporate watchdogs to make sure that corporations run efficiently. Of course, some stockholders fail to pay proper attention to their corporate officers. But many stockholders do pressure corporate executives to run their businesses more efficiently, and this pressure contributes to the overall efficiency of the economy.

**STOCKS, RESTRICTED AND UNRESTRICTED**

Restricted and unrestricted stocks are important components of corporate executive compensation packages. Restricted stocks have particular conditions that must be fulfilled before they can be transferred or sold, whereas unrestricted stocks have no such conditions.

There are two types of restricted stocks. The first type is often referred to as unregistered stocks, which are not legally registered with the Securities and Exchange Commission (SEC) for the purpose of public transactions. The Federal Securities Act of 1933 requires that all stocks be registered with the SEC prior to any public transaction unless the transaction or the stocks are exempt. In 1972 the SEC implemented Rule 144, which identified restricted stocks as any privately issued company stocks, or company stocks publicly purchased by company “insiders” (powerful employees like company executives). According to the SEC, restricted stocks must be held for a certain period of time before they can be publicly sold. However, restricted stocks may be sold privately at any time, though such transactions are strictly regulated.

Restricted stocks are commonly used in executive compensation packages to ensure a balance of long- and short-term incentive rewards. Whereas unrestricted stocks are often considered to be short-term incentive rewards
because they can be immediately sold, restricted stocks are usually considered to be long-term incentives given the length of their vesting periods (the length of time the stocks must be legally held before they can be publicly sold). However, there is disagreement about the actual effectiveness of restricted stocks as long-term incentives. Restricted stocks are also often granted to insiders after corporate mergers and acquisitions to prevent adverse effects on company performance. Venture capitalists are also often given restricted stocks in pre-initial public offerings to help ensure long-term commitment.

The second type of restricted stock is also commonly used in company compensation plans as incentives or rewards for employee performance or service. These stocks are similar to unrestricted stocks in the sense that they are not legally restricted. However, they are restricted in the sense that they cannot be transferred or sold by employees until they have fulfilled certain conditions set by the company. These conditions are often related to specific employee performance goals or are satisfied after an employee remains with a company for a set period of time. For example, a company may grant one thousand shares of restricted stock to an employee who can sell those shares when a certain performance goal is fulfilled. Alternatively, it may grant one thousand shares of restricted stock to an employee who can sell those shares two years after the date the shares were issued.

Although both restricted and unrestricted stocks have long played a role in executive compensation packages, the popularity of restricted stocks increased dramatically in the United States after the passing of the 2002 Sarbanes-Oxley Act, which required companies to expense stock options granted to all employees through compensation plans. The act followed a wave of corporate scandals between 1999 and 2001 in which prominent company executives at companies like Enron, WorldCom, Tyco, and Adelphia artificially inflated their company’s stock prices to cash in their stock options for their own financial gain.

STOCKS AND FLOWS

In economics and business, the concept of stocks and flows is crucial to understanding the development of economic variables. It is most commonly used in macroeconomics, labor economics, and accounting. More generally, the concept of stocks and flows is central in system dynamics theory, which describes the development of complex systems.

Most economic variables are either stocks or flows. Stock variables describe the state of the economy at a given point in time, whereas flow variables describe the changes in the economy over a period of time. If one looks at an extremely small period of time, flows will be close to zero, whereas stocks could have any value. Stocks are accumulated or depleted over time by flows, whereas flows represent the rate of movement of items in and out of stocks. Frequently, stocks are characterized by nouns and flows, which represent processes, by verbs.

Flows can be divided into inflows—flows that add to stocks—and outflows—flows that deplete the stocks. The difference between inflows and outflows is called net inflows. The figure illustrates the relationship between stocks and flows. If the inflow is greater than the outflow or net inflow is positive, the stock will be rising; if the inflow is less than the outflow, net inflow is negative, and the stock will be falling.

The simplest illustration of stocks and flows is a bathtub. The level of water in the bathtub is a stock, the water coming from the faucet is an inflow, and the draining of the water through the drain is an outflow. If we plug the drain and turn on the faucet, the net inflow will be positive, and the stock of water in the bathtub will be rising. If, instead, we close the faucet and open the drain, the net inflow of water will be negative, and the stock of water in the bathtub will fall.

STOCKS AND FLOWS IN MACROECONOMICS

Economic development cannot be well described or understood without knowledge of which variables represent stock and which variables represent flows. Most macroeconomic variables reported by statistical agencies are flow variables. Gross Domestic Product (GDP) represents the value of final goods produced by the economy.
during a given year. GDP is a flow that is measured in dollars, euros, or other currency units per year. GDP is an inflow to the stock of inventory in the economy. The stock of inventory is not large as most of GDP is either consumed by individuals or by the government, invested in production by firms, or exported. Consumption, government spending, and exports are outflows. The remaining GDP is accumulated as additional inventory.

An important stock that plays a big role in macroeconomics is a stock of government debt. It is accumulated by the flows of government budget deficits (the difference between budget spending and budget revenues); it is depleted by the repayment of the debt, through budget surplus (negative budget deficit). If the government runs a budget deficit for many years in a row, it will accumulate a large stock of government debt. Because the interest needs to be paid on the stock of debt and the interest payments are part of budget spending, it becomes harder to stop accumulating the debt when the stock is already large. This provides an example of how the stocks themselves can affect the flows: the larger the stock of debt, the larger the interest spending that is a flow contributing to the stock of debt.

Another important example of stocks and flows in macroeconomics is unemployment. At any given point in time a number of people in the economy are unemployed. The total number of unemployed is a stock. In each period a number of people lose their jobs and join the ranks of unemployed, representing an inflow to unemployment, and a number of unemployed people find jobs and leave unemployment, representing an outflow from the unemployment. If the rate at which workers lose their jobs (job separation rate) is higher than the rate at which unemployed find jobs (job finding rate), unemployment will increase because the net inflow to unemployment will be positive. Thus policies designed to lower the unemployment rate must take into account the effects of certain measures on both job finding rate and job separation rate. For example, if a policy makes it harder for firms to fire workers, it would lower the job separation rate. However, such a policy would also make firms more reluctant to hire new workers, lowering the job finding rate. The overall effect of such a policy on unemployment is uncertain.

STOCKS AND FLOWS IN MICROECONOMICS

Each individual’s wealth is a stock. It is accumulated by the inflow of income and depleted by the outflow of spending. The best way to picture this is by thinking about a bank account. The balances in the bank account represent the stock of cash available to the individual; the direct deposit of the salary is an inflow to the account, and check and cash withdrawals are the outflow. If the net inflow is positive, the balances in the bank account will rise. Of course, individuals can hold other assets in addition to bank accounts. Frequently, the largest portion of an individual’s wealth is the value of his or her house. Economists believe that the stock of wealth affects the flow of consumer spending—the higher the wealth, the larger portion of income the consumers are willing to spend, which lowers the net inflow of income. This is a mechanism through which economists at the beginning of the 2000s linked the U.S. housing boom to the nation’s low savings rate.

Firms also have a stock of wealth, usually referred to as the firm’s net worth, or capital stock, which is the difference between a firm’s assets and liabilities. If a firm is publicly traded, individuals and financial institutions can buy shares of that firm’s stock, which would give the buyer an ownership share of the stock of the firm’s wealth. Firms accumulate their capital through the inflow of investment. The stock of capital depletes through the outflow of depreciation and capital that is used up in production.

Galina Hale

STOLEN GENERATIONS (AUSTRALIA)

Stolen Generations, a term coined by Australian historian Peter Read in 1981, refers to those Australian Aboriginal and Torres Strait Islander people who were taken from their indigenous families and communities as children. In its widest interpretation, Stolen Generations might encompass all those indigenous children taken away from their communities since the earliest days of British settlement to the present day, but it is more generally understood to refer to the estimated 100,000 people taken forcibly under extraordinary government legislation targeting children of Aboriginal descent.

Such legislation was first enacted in the 1880s by the Victorian colonial parliament, as the key to its aim of concentrating “full-blood” Aboriginal people, presumed to be on the verge of extinction, on reserves, while forcing off those of mixed descent. Similar legislation was enacted around Australia by the six state governments after federation in 1901, enabling removal and indenturing of Aboriginal and mixed-descent children at the discretion of the authorities, without requiring parental consent or a court ruling. The national Commonwealth government, taking over administration of the Northern Territory in 1911, demonstrated its own commitment to indigenous child removal by introducing such legislation itself. These early policies were couched as “protection.” Introduced in
response to Aboriginal land reservation in the southeastern states, child removal under this legislation peaked in the 1920s in accompaniment with a second dispossession as these reserved lands were revoked. Focusing disproportionately on girls, who were placed in private domestic service, the practice revealed an intent to “absorb” the Aboriginal population by removing their children to be brought up as “white.”

Authorities used the threat of child removal to ensure submission on the now government-controlled reserves, though the child of any person of Aboriginal descent could be taken. Where white settlement was sparser, child removal accompanied the expansion and consolidation of white control, alongside violent destruction of Aboriginal communities, and tended to target children of non-Aboriginal fathers to prevent the growth of a mixed-descent Aboriginal population. Institutions were established around Australia to hold removed children. Aboriginal organizations in the southeast protested, and attempted to raise wider awareness and support in the interwar period, with feminist and humanitarian organizations playing a role in campaigns against child removal.

An important conference of state and federal Aboriginal authorities held in 1937 partly in response to such criticisms prefigured a postwar shift to “assimilation.” The influx of non-British migrants from former enemy lands and a shift to cultural theories of race created a new emphasis on the social assimilation of Aboriginal people to an “Australian way of life,” even as Australia ratified an international treaty that defined forcible removal of children as a crime in international law in 1949. Boys were now taken in equal proportions to girls, and adoption to white families replaced the older systems of institutionalization and apprenticed labor. Though indigenous people might claim exemption from the provisions of government legislation, subject to proof one had assimilated by having cut ties with the broader indigenous community, a parent’s exemption certificate did not cover the children. Indigenous children continued to be arbitrarily removed on no other grounds than their race for decades, with repeal of such discriminatory legislation only starting in 1964, and continuing, slowly, until the last was removed in 1984. By that time, generations of indigenous children had been removed from their families and communities. While many would eventually return to the broader Aboriginal and Torres Strait Islander community, the effects of repeated dislocations, disruption, and trauma were immense, for individuals and for the diverse indigenous communities around Australia. The impact of child expropriation on indigenous Australia has been as devastating as that of land dispossession, if not more so.

Australia entered the millennium with the Stolen Generations at the forefront of political debate. The 1997 Report of a National Inquiry into the Separation of Aboriginal and Torres Strait Islander Children had found that the “actions were genocidal,” a number of civil cases had been fought and lost, and there were calls to make restitution a part of the process of national reconciliation. Approximately 250,000 people walked across the Sydney Harbor Bridge in 2000 on Sorry Day, one of the largest public demonstrations in Australian history. State governments and other groups formally apologized to Aboriginal and Torres Strait Islander people. Prime Minister John Howard controversially refused to apologize, arguing that an official apology might constitute liability for compensation claims. Though the term itself was fiercely contested, the history of the Stolen Generations nevertheless became part of the curricula in many schools.

**STOLPER-SAMUELSON THEOREM**

In 1941 Wolfgang Stolper (1912–2002) and Paul Samuelson (b. 1915) put forward a proposition relating changes in the real incomes of workers and of capitalists to changes in the level of protection from import competition. They showed that lowering protection lowered the real income of the scarce factor used intensively in the import-competing sector and raised the real income of the other factor. Previously, international economists believed that opening an economy to international trade would, by increasing the aggregate supply of goods available, enable all income earners to be better off.

Victoria K. Haskins
Stolper and Samuelson constructed a model of an economy in which only two factors, capital and labor, are used to produce two goods. Households either own capital or supply labor. The home economy cannot change world prices, but it can change the relative price of the two goods by changing the taxes levied on the imported good. In a neoclassical economy in which prices adjust smoothly and all factors are fully employed, a change in goods prices induces a change in the real income of the households owning the factors that produce the goods so that one group of factor owners is better off and the other is worse off.

The crux of the theorem is the link between the changes in the relative price of the goods and the changes in the prices of factors thereby induced. Since 1941 other international economists have stressed that this link has nothing to do with factor scarcity or the cause of the change in goods prices, but rather that it applies generally whenever relative price changes. The importance of the theorem derives from its fundamental message that changes in goods prices necessarily create conflict between households owning different factors. A vast literature developed in response to Stolper and Samuelson seeking to generalize the theorem to a world in which there are many goods and many factors. However, unless very strong restrictions were imposed on the technology of the producers, generating general propositions linking factor income changes to goods price changes proved difficult.

A later model that uses a criterion of real income change corresponding to the change in the utility of the income earner has obtained general propositions. Subject to a weak restriction that there is some diversity among households in their preferences and/or their ownership of factors, a change in any goods price will make some households better off and some worse off. Conversely, for any household there is some goods price change that will make it better off and some that will make it worse off. This generalizes the essential message of the original theorem. It shows that there are universal incentives for households to lobby government to change policies to yield benefits for them, and for other households to oppose them.

As an example, take the original Stolper-Samuelson model in which two factors produce two goods. Suppose the shares of capital and labor in the costs of producing a unit of good 1 (clothing) are $6/10$ and $4/10$ respectively and that the corresponding shares in producing a unit of good 2 (machinery) are $3/10$ and $7/10$. Thus, clothing is the good that uses a relatively labor-intensive technique of production. Then, if the price of clothing is raised by 1 percent, the wage rate of workers goes up by 2.3 percent, and the rate of return on capital goes up by 2 percent. As predicted by the theory, both workers or capital-owners will benefit if the price of the good which uses their factor intensively rises because of some government intervention in markets.

The theorem has applications to changes in goods prices that originate because of changes in any government taxes or policies or supply shocks. In particular, the theorem is the foundation of models of political economy that seek to explain patterns of government taxes and expenditures. It has been applied empirically to models that explain the structure of national tariffs, other taxes, subsidies, and transfers to households.

**STORYTELLING**

*Storytelling* may be broadly defined as an ancient method of conveying ideas, intimations, and emotions in a narrative form with or without the accompaniment of music or visual art. Originally an oral tradition, storytelling has evolved from its earliest form to include a variety of multimedia applications. Folklorists generally do not approve of such inclusive definitions. In her scholarly analysis of the history of storytelling, *The World of Storytelling* (1990), Anne Pellowski defines storytelling as:

the art or craft of narration of stories in verse/and or prose, as performed or led by one person before a live audience; the stories narrated may be spoken, chanted, or sung, with or without musical, pictorial, and/or other accompaniment and may be learned from oral, printed, or mechanically recorded sources; one of its purposes may be that of entertainment. (Pellowski 1990, p.15)

Storytellers may have also collected stories from various people they encountered while telling the stories they
had learned or created from observations and life experiences. Stories may have been used to entertain, but they were also used to educate audiences. Folklorists discuss oral tales of two main types: *Märchen* and *Sagen*, which are German terms with no exact English equivalents. *Märchen* is both singular and plural, and means something akin to *fairytale*. These tales, which are not presented as true, are set in the timeless/placeless world of *once-upon-a-time*. The *Sagen*, or legends, however, are presented as factual, with powerfully specific times and places. The common folk may have told their stories at home, at work, and at festival times. Folk stories were told repeatedly and handed down through generations from one teller to the next, making use of storytelling for teaching purposes. Collectors of folktales, such as the Brothers Grimm, Charles Perrault, Joseph Jacobs, Peter Christian Asbjørnsen, Jorgen Moe, Andrew Lang, Joel Chandler Harris, and Richard Chase seem to have gathered tales, in part, for the purpose of cultural enrichment.

What is the purpose of storytelling? Pellowski, in line with other theorists, says that storytelling may have started as informal entertainment or play, and only gradually became intertwined with religious rituals, historical recitations, and educational functions. Most theorists suggest that storytelling fulfills the desire for playacting and meets entertainment needs while helping to explain the surrounding physical world or helping honor or placate the supernatural force(s) believed to be present in the world. Storytelling can help explain and express strong emotions and experiences in memorable, long-lasting ways through the intricate use of rhythm, rhyme, and repetition. Storytelling can help preserve traditions, customs, and societal standards, while bestowing immortality on leaders or ancestors. Pellowski notes the earliest evidence of storytelling may be found in the Westcar Papyrus of the Egyptians, which includes tales of encounters between a pyramid builder named Khufu or Cheops and his sons. One of the most famous tales recorded on papyrus is known as *The Shipwrecked Sailor*.

Pellowski traces the development of the bardic tradition, defining the bard as, “a storyteller whose function is to create and/or perform poetic oral narrations that chronicle events or praise the illustrious forebears and present leaders of a tribal, cultural, or national group” (Pellowski 1990, p. 21). The bard was a storyteller, a poet, and a musician. The term *bard* had its introduction through Greek and Roman tales of the Celts. Bards have also been known as *rhapsodes*, *minstrels*, or *jongleurs*.

Tales from a variety of cultures have been preserved because of storytelling traditions. Some examples are: *Beowulf*, an Anglo-Saxon tale of courage in the face of brute strength; *Gilgamesh*, a Sumerian epic tale of the Sumerian king, Gilgamesh, and his friendship with Enkidu, the half-beast, half-man being created to destroy him; *The Iliad*, a Greek epic tale of the Trojan War; *The Odyssey*, a Greek epic tale of Odysseus on his homeward journey from Troy; *Story of Sigurd (Siegfried)*, a Norse legend; *The Volsunga Saga*, the adventures of Sigurd, including the killing of a dragon named Fafnir; *The Merry Adventures of Robin Hood and King Arthur and His Knights*, legendary English tales of daring and bravery; *Song of Roland*, legendary French tales; *Sundiata, The Epic of the Lion King*, a legendary African tale of how Sundiata became King of Mali; *The Tain*, an Irish tale of the legendary hero Cuchulain, his birth, battles and ultimate death; and *The Ramayana* of India, a religious tale.

**STOWE, HARRIET BEECHER**

1811–1896

As an active figure of the nineteenth century and the so-called “feminine fifties,” Harriet Beecher Stowe lived and wrote, negotiating between extremes of unfolding cultural elements. During that time, young girls commonly learned that the meek could and should inherit the world by practicing self-discipline and humility. As they matured, women might learn that they could through their own wit and activity earn a place in an emerging capitalist economy. Stowe’s life and writings approach such cultural contradictions as played out in the realms of race, sex, class, religion, and changing ideas of what constitutes noble identity and behavior.

Stowe’s best-selling *Uncle Tom’s Cabin*; or, *Life Among the Lowly*, first appeared as serialized in 1851–1852 in the abolitionist newspaper *The National Era*. In 1852 these “sketches” were published in book form and widely translated into theater and over forty languages. As Stowe states in her preface, “The object of these sketches is to awaken sympathy and feeling for the African race, as they exist
among us; to show their wrongs and sorrows, under a system necessarily cruel and unjust.” Appealing to her readers’ various faculties, Stowe shows that the institution of slavery is fundamentally incompatible with Christianity. By 1862 when she met with President Abraham Lincoln, the cultural impact of Uncle Tom’s Cabin had become so great that Lincoln is said to have acknowledged, “So you’re the little woman who wrote the book that started this great war!”

Public reaction to Stowe’s million-seller in large part reflects debates in American racial history. After receiving scathing contemporary pro-slavery reviews, she documented her sources by publishing the five-hundred-page A Key to Uncle Tom’s Cabin (1854). Later, Harlem Renaissance writers and others have sharply criticized Stowe’s Christ-like portrayal of the martyr Uncle Tom as obsequious and a role model obstacle in the struggle for racial equality.

Born on June 14, 1811, Stowe’s early life prepared her well for facing slavery and women’s issues head-on and resolutely. She gained rhetorical skills early from her austere and demanding Protestant evangelist father, Lyman Beecher, and later from her brother, abolitionist and theologian Henry Ward Beecher. Available to her were books, sermons, and philosophical discussions. In a home populated by siblings, relatives, and boarders, she developed a lively mind as well as a reverence for an idealized image of womanhood. Stowe attended the Hartford Female Seminary—founded and run by her sister Catherine Beecher—and later taught there. Unlike other women’s schools that prepared women for marriage, Beecher’s seminary taught women to use their own judgment and to become socially useful. Such teachings evolve as a concluding lesson in Uncle Tom’s Cabin as readers are urged to see to it that in their actions they “feel right.” In 1836 Harriet Beecher married the Bible scholar Calvin Ellis Stowe and subsequently bore seven children before moving to Bowdoin, Maine, in 1850.

Later in life Stowe spoke and wrote to protect the women’s rights movement from those who advocated free love and free divorce. Her later works question the cultural bases of capitalism and consumerism by revisiting the early 1850s virtues of humility, charity, self-discipline, and social usefulness, but these works generally lack the fire that had established her earlier place in literary history. She died on July 1, 1896.

**STRATEGIC BEHAVIOR**

In economics, the term *strategic behavior* usually refers to decision-making that takes into account the actions and reactions of other economic agents. Its essential feature is the recognition of the direct interdependence between one’s behavior and that of others.

The difference between strategic and nonstrategic behavior can be highlighted by the following example: Suppose a consumer enters a store and encounters a product with a particular marked price. This consumer’s decision to buy or not buy the product depends solely on their preference for the product. On the other hand, suppose the store allows bargaining. In this case, the price for the product is not fixed, but depends rather on the process of negotiation between the buyer and the seller. In this process of negotiation and purchase, the consumer presumably not only takes into account their own likes and dislikes for the product, but also tries to anticipate such factors as the lowest price the seller would be willing to accept. Whereas in the first situation personal preference is the only factor influencing the consumer’s decision, in the latter case the consumer also has to take into account the seller’s behavior in deciding what offer to make or accept and consequently whether to buy or not. This latter process is an example of strategic behavior.

In economics, the first formal discussion of the concept of strategic behavior is believed to be in Augustin Cournot’s 1838 book *Recherches sur les principes mathématiques de la théorie des richesses* (published in English as *Researches into the Mathematical Principles of the Theory of Wealth*). In a chapter on the competition between producers, Cournot considers how each producer, when making output decisions, takes into account the impact their own output and that of other producers has on the market price and thereby on profits.
The concept of strategic behavior is now recognized in many diverse academic fields, ranging from economics and business to politics and international relations. In the present day, a counterpart of Cournot's above-mentioned example with an impact on our day-to-day life is competition between producers of oil. There are only a handful of big oil-producing countries in the world, and in deciding whether to increase or reduce production, each takes into account the impact of their decision on the price of oil in the global market and consequently on their own revenues. R&D races, bidding in auctions, trust in societies, contracts, and social insurance are a few of the many prominent applications of the concept in economics and business. Strategic voting and the formulation of election platforms are two examples of strategic behavior in politics, while in international relations, strategic behavior is found in arms races, trade, and in negotiations between nations. The outcome of interaction between the strategic behaviors of a set of agents is a subject examined by game theory.

STRATEGIC GAMES

The concept of a strategic game forms part of the central idea behind the theory of games. A strategy is a plan of action that a player can use to guide the player in selecting moves throughout the game. It may be trivially simple, such as "whenever you are called on to move, select randomly among the moves," or it may contain detailed complex instructions to cover all contingencies.

With few exceptions, virtually all games of any interest have a strategic component. Even tic-tac-toe, which is often utilized to illustrate an inessential game, or one that is not worth playing, has a strategic component. It is regarded as inessential because with only a little thought both players can enforce a draw; nevertheless, it has a set of strategies from which each player can select his actions. Even in a game as simple as this it is possible to select a losing strategy.

In the formulation and mathematical analysis of games of strategy, John von Neumann and Oskar Morgenstern (1944) made the great contribution of providing a complete language for the study of individual and multiperson conscious strategic choice. Concepts that had been extremely vague were defined precisely and operationally in a manner so that they could be analyzed mathematically. This includes the precise meanings of the terms choice, move, information, strategy, outcome, and payoff. But in many of the social sciences, particularly political science, sociology, and anthropology, some research questions are rather abstract, taking into account context and much of the richness and intangibles of areas of investigation. For many of the critical problems in the disciplines these subtleties cannot be ignored, and unfortunately the formal language of strategic games does not pick them up. With its mass markets and anonymous rational conscious behavior, economics has many more questions that are congenial to the strategic game analogy than do the other social sciences.

When the analogy is made between formal games of strategy and strategic behavior in politics or society, the gap between them is manifested in the assumptions that are made concerning knowledge of the rules of the game and common knowledge. When we consider the game chess, two implicit assumptions are made: It is assumed that all players know the rules of the game, and that each player knows that the other player knows the rules of the game. In society, even the best politicians know that much is unknown.

In the formal definition, strategy is defined as a complete book of instructions that a player could give to a delegate to play for him that describes what he wants the delegate to do under every contingency that might arise. A game as simple as chess has a hyper-astronomical number of strategies, so large that there is no way that they can all be enumerated in practice. It is clear that chess could be considered an inessential game in the sense that if a player could calculate all strategies it would be simple to select an optimal strategy, and if each player did that he would not bother playing—he would merely submit his optimal strategies and the game would be declared a draw or a win for the first mover. Yet years of experience and calculations on the size of the calculations tell us that the way chess is actually played by the best of human chess players is not by the enumeration of all strategies.

The difference between the abstraction of certain concepts and their manifestation in everyday life is nicely illustrated in the formal concept of strategy and how it is manifested in both military and corporate arenas. A strategy in the military or at the top of a corporation is an overall plan that, in its scope, bears some resemblance to the ideal strategy utilized in strategic games, but it has at least two critical modifications: It recognizes the critical role of delegation and aggregation. The general knows
that neither he nor his opponent knows all the rules of the
game, and he knows that he has to delegate decision-making
to those who have greater special information than he does.

In spite of these caveats, there are many questions in
economics, political science, social psychology, and even
law, biology, and anthropology that can use the formal
game structure profitably. Two basic applications to polit-
cical science serve as examples. The first is the Condorcet
Paradox and the second the Shapley-Shubik Power Index.

The Condorcet Paradox was established in 1785 by
Marquis de Condorcet (b. 1743). His Essay on the
Application of Analysis to the Probability of Majority
Decisions describes describes the intransitivity of majority
preference. According to the Condorcet Paradox majority
wishes can be in conflict with each other. Consider three
individuals named A, B, and C and the issues called I, II,
and III to be put to the vote. The preferences of A are
given by I pr II pr III (where pr means “preferred to”), the
preferences of B are III pr I pr II, and the preferences of C
are II pr III pr I. Consider a simple majority vote between
two any two social choices. By a 2:1 majority, a vote between
I and II selects I, a vote between I and III selects III, and
a vote between II and III selects II.

The Shapley-Shubik Power Index (Shapley and
Shubik 1954) gives an intrinsic measure for how power
varies with the accumulation of votes. Consider a com-
mittee with five votes. If there are three individuals with
one person having three votes and the other two people
having one each, and the rule was simple majority vote,
the individual with three votes would have all the power.
If there were five individuals, each with one vote, the
power would be spread evenly. The index gives the non-
linear formula to measure power as a function of distribu-
tion of the votes. For example, in the five-vote
simple-majority voting game, if there were four individu-
als with one having two of the five votes and the others
having one each, the first person’s power would be one-
half, and the others’ would be one-sixteenth each. This
measure provides a benchmark, assuming that all individ-
uals have equal chances of forming any coalition. In applica-
tion, a correction for coalition possibilities must be
made. A natural application of this is in predicting out-
comes in Supreme Court cases.

STRATEGIES, SELF-
HANDICAPPING

People might be expected to reach for any and every
advantage to facilitate performance, including eliminating
any obstacle or disability that might interfere with success.
Nevertheless, individuals are sometimes willing to strate-
gically create impediments to performance, and this has
been termed self-handicapping. Self-handicapping is a
strategy undertaken to escape the implications of an
impending failure, should it occur, on an individual’s
sense of self-worth. It is an anticipatory self-protective
strategy, the goal of which is to guide performance-rele-
vant attributions. Those who make use of this tactic place
excessive significance on ability. They feel that compe-
tence can be demonstrated but not improved, and while
they perceive their own self-worth as hinging on personal
aptitude, they are uncertain of their capacity to succeed.
Thus, self-handicappers possess a fragile, doubt-ridden
sense of self, which they work to bolster. By erecting bar-
rriers to achievement, self-handicappers aim to discount
personal competence as the causal agent in any subse-
quently failure. The presence of such obstacles also serves
to enhance any personal responsibility for successful out-
comes occurring in spite of the handicap.

Two distinct forms of self-handicapping have been
investigated: behavioral and claimed. Behavioral handi-
caps involve actively sabotaging one’s own performance.
The athlete who fails to practice in the weeks leading up
to an important match may be using lack of preparation
as an explanation for an impending loss. However, an ath-
lete who complains of illness, fatigue, or injury prior to a
match may satisfy the same goal of providing a justifica-
tion for failure, but these are merely claims, where the
individual does not actively undermine his or her per-
formance, but instead provides an a priori excuse. In gen-
eral, males are more likely to engage in behavioral
As originally conceptualized, self-handicapping was thought to stem entirely from an individual’s desire to sustain positive self-views. However, research shows that impression management or maintenance of esteem in the eyes of others is also an influential motive. As such, self-handicapping can involve self-deception as well as self-presentation.

Some individuals are more likely to employ this strategy than others. Situational factors can also increase the likelihood that self-handicapping will occur. Most notably, situations involving noncontingent success (e.g., undeserved praise, inexplicable victory) or private failure are also more likely to induce self-handicapping. Earned or expected successes are liable to be seen as repeatable (and thus are unlikely to produce the feelings of uncertainty necessary for self-handicapping). Further, whereas private failure leaves open the possibility of being viewed positively by others, public failure leaves no positive image to preserve, and makes the introduction of additional handicaps useless.

Though employed as a means to protect the self from undesirable consequences, in the long run self-handicapping may actually cause more harm than it prevents. Some handicaps are injurious in and of themselves (e.g., drug and alcohol abuse). Further, although self-handicapping does bolster immediate self-regard, habitual use of this strategy actually undermines self-esteem by underscoring a person’s self-doubt. In addition, high self-handicappers tend to demonstrate poorer academic performance. Ironically, the desire to appear capable seems to actually drive self-handicappers to undermine their competence over time.

STRATEGY AND VOTING GAMES

In game theory, a player’s strategy refers to a complete contingent plan for all possible scenarios that might arise. When voting is modeled in a game theoretical framework, voters are treated as strategic players, and the framework describes the strategic interactions among the voters. A voting game is characterized by three key elements: the set of voters, the set of strategies available to each voter, and each voter’s preferences on the set of voting outcomes. The set of feasible strategies in a particular voting game depends on the voting system in use. For example, under the plurality voting system, each voter can vote for only one candidate. With preferential voting, each voter ranks a list of candidates in order of preference. Therefore, a voter’s strategy in a plurality voting game specifies which candidate to vote for each combination of other players’ votes, whereas in a preferential voting game, a strategy specifies a preference list for each combination of other players’ rankings. A voting outcome is determined by all voters’ strategies (called a strategy profile) under a particular voting system. For example, in a single-winner plurality voting game, the candidate with the most votes wins the election. In proportional representation systems, the percentage of votes received by a party determines the percentage of seats allocated to the party. A voter’s preference on the set of voting outcomes is usually represented by a payoff function that assigns a numeric value to each strategy profile.

The concept of strategy, together with strategic game (or normal form game), was first formally introduced in 1944 in The Theory of Games and Economic Behavior, by John von Neumann and Oskar Morgenstern. Later, in 1950, John F. Nash Jr. developed the solution concept of the Nash equilibrium, which describes any stable state in which each player’s strategy is optimal (in the sense that it maximizes a player’s payoffs among his or her other strategies) given other players’ equilibrium strategies. Since then, game theory has become an important tool for analyzing problems in various fields, including economics, biology, and political science. An early application of game theory to voting situations was offered by Robin Farquharson in his influential 1969 book, Theory of Voting. Farquharson’s approach departed from earlier studies, which usually assumed sincere voting by disregarding the strategic aspects of voting. A voter’s strategy is sincere if the person votes according to his or her true preferences regardless of other voters’ strategies. In general, a sincere voting profile does not constitute an equilibrium for a voting game. Allan Gibbard (1973) and Mark Allen Satterthwaite (1975) proved a theorem showing that strategic voting is universal in common democratic systems. Consequently, modeling voting as a
Strategic game has been widely accepted in economics and political science.

Although strategic voting modeling has its theoretical attractiveness, the degree of empirical support varies for different voting systems. In addition, two lines of criticism of game theoretical voting models have arisen. From a descriptive view, it is not clear whether real-life voters have full knowledge of game structures and are able to perform complex strategic calculus. Normatively, strategic voting rationalizes manipulations of systems by voters who misrepresent their preferences, and accordingly by candidates who use media influence to shape voters' perceptions. Such manipulations are generally considered undesirable for a democratic system.

STRATIFICATION

The term *stratification* refers to the system of inequalities within and between societies, the processes of assignment to positions within a social hierarchy, and the means by which resources are allocated. Various theories have tried to explain how and why stratification systems emerged. The most prominent of these were developed in the nineteenth and early twentieth centuries following industrialization, which altered the social structures of traditional feudal and agrarian societies and gave rise to more complex urban societies. Before industrialization, societies were more stable and had much less economic inequality, and clear, fixed boundaries separated groups like the nobility from their subjects (see Lenski 1966).

In his pioneering account, Karl Marx explained stratification as a product of the mode of production—the principal system of market organization (e.g., capitalism). He outlined a progressive transition from feudalism to capitalism and finally to socialism. Marx claimed that the organization and development of modern, industrial capitalist societies were driven by class relations. He argued that capitalist societies would grow increasingly divided between a capitalist class that owns the capital and therefore controls the means of production and a growing labor class (proletariat) that sells its labor to capitalists in order to survive. Marx predicted a struggle between capitalists and workers leading to the destruction of the capitalist system and the formation of a socialist society free of classes. Moving beyond his historical prediction, modern Marxists have reconceptualized his class schema to focus on authority, the inherently antagonistic relations between workers and owners/managers, and the exploitative nature of capitalism (see, for example, Wright 1997).

In the early twentieth century, Max Weber added a focus on social status and political power to Marx's more purely economic perspective. He proposed class, status, and party as the three dimensions of stratification in modern societies, though he also discussed the role of castes and professions. Though Weber's writings conceptualizing class were not very developed or novel, he has been deployed widely in class schemas focused on prestige, occupations, status, and skill. Weber’s present-day influence can most be seen in the use of his concept of closure—that is, the process by which organizations define boundaries that establish which members receive certain benefits and which do not.

Structural functionalism, which traces its roots to the work of Émile Durkheim, perceived stratification systems as universal to every society, from simple hunter-gatherer tribes to complex, modern industrial societies. Kingsley Davis and Wilbert E. Moore (1945) offered a particularly influential account of the “functional necessity of stratification.” Structural functionalist theories were criticized for neglecting conflict and for failing to address the possible lack of stratification in small egalitarian tribes or the reduction of stratification in modern social democracies. Today, structural functionalism has few followers in the social sciences.

A common characteristic of these early attempts was the effort to develop general laws. During the post–World War II (1939–1945) period, however, social scientists have moved away from grand, all-encompassing theories of stratification toward more flexible perspectives, which perceive stratification as a result of the interplay between multiple actors and multiple dimensions of inequality. One of the main new issues gaining attention was that of gender. Scholars argued that gender played a central role in the formation and functioning of stratification systems. They showed that women’s exclusion from social life
placed them in an inferior position, resulting in lessened life chances and status. While women’s standing in social and economic life has improved over the past half-century, women are still restricted by gender roles and patriarchy. Rich literatures examine the impact of family structure, occupational segregation, devaluation of women’s work, and sex-based pay gaps.

Other issues that came under greater scrutiny were race and ethnicity. Scholars demonstrated that one’s racial and ethnic background greatly influences one’s life chances. U.S. sociologists have devoted a great deal of attention to black-white differences in residence, educational achievement, and employment status. Many focused on residentially segregated ghetto communities where unemployment, poverty, and single parenthood were highly concentrated. Though many sociologists have demonstrated that some racial and ethnic differences can be explained by class-based factors like income level, there is an emerging literature on how race, gender, and class intersect to shape disadvantage.

There also has been great interest in the actors and processes that reproduce and maintain social inequalities. Many sociologists focused on the role of elites in the reproduction and maintenance of social inequalities. American sociologist C. Wright Mills (1956) argued that a “power elite” controls the economy, state, and military. Some scholars have described elites as a conscious, homogenous social class, which actively reproduces itself and guards the privileges it possesses. Perhaps the most productive line of inquiry has concentrated on the linkages between social origins and levels of attainment. Peter M. Blau and Otis Dudley Duncan (1967) famously analyzed the relationship between paternal occupation, education, and attained occupation. Debates about modeling techniques and historical and cross-national patterns of mobility and attainment dominated analyses of stratification from the 1970s to the early 1990s. Some scholars took the study of reproduction, mobility, and attainment in new directions and emphasized the role of social ties and culture. French sociologist Pierre Bourdieu argued that access to high culture and learned practices, which he referred to as cultural capital, enable the children of the privileged to get ahead and facilitate the reproduction of social inequalities. Bourdieu also offered the concept of habitus to account for the embodied disposition that dominant classes exercise instinctively to reproduce their higher status. The concept social capital emerged to refer to the resources that flow through social networks.

In recent years, with the rise of globalization and the expansion of neoliberalism across the globe, debates about the global stratification system gained a great deal of attention. World systems theorists, led by Immanuel Wallerstein, contend that industrial core countries have an exploitative relationship with the less-developed periphery. The perseverance of poverty in the Third World, the weakening position of traditional labor classes in industrialized countries, and rising income inequalities within nearly every country lead many to believe that we are now facing a global system benefiting a small minority while hurting the rest. While many note the massive levels of inequality between countries, there has been a lively debate about whether global inequality is increasing or decreasing. Glenn Firebaugh (2003), for example, claims that inequality between countries has decreased, while Branko Milanovic (2005) contends it has increased. Regardless, global inequality in income, health, and well-being remains enormous and in the future stratification scholars are likely to focus more on the plight of the disadvantaged in less-developed countries, where the majority of the world’s population resides.

STRATIFICATION, POLITICAL

If social stratification usually refers to the kind and degree of distribution of resources (e.g., wealth, status, prestige, and privilege) within a social system, then political stratification is best understood as the extent to which such inequalities are encapsulated in, or influenced by, political structures and processes (i.e., involving influence, authority, or power). In this sense power is understood not only in relation to achieving desired results, even against opposing interest, but also in terms of the ability to frame and set agendas. Conceived of and measured as an absolute, or relative, entity, political stratification is often used in studies on societal change, egalitarian opportunity structures, democratization, the distribution of power and equality, and the efficiency of social and political justice. Linking political, economic, and social inequality structures, the concept is central to the social sciences and social policy.

Narrower conceptualizations of political stratification, favored particularly by political scientists in the 1960s and 1970s, usually focus on stratified political activities, positions, and influence of individuals, groups, parties, or nation-states. Studies in this vein tend to explore a variety of topics including political elites, the electorate, perceptions of democracy and citizenship, political activism, and new social movements. However, this narrow conception is rarely accompanied by a clear overarching theoretical model about political stratification. Indeed, attempts to distinguish political from social stratification are only partially successful and not widely accepted in the social sciences, due in part to the complex yet profound interdependence between the political, social, economic, and cultural spheres. Political stratification in a wider sense, however, has permeated the social and political sciences. Indeed, most modern studies on social stratification are steeped in a political discourse.

POLITICAL STRATIFICATION FROM AN INSTITUTIONAL PERSPECTIVE

From an institutional perspective political stratification can be related to norms, values, class structures, status groups, associations, and laws, which structure the relations between individual and collective actors. For example, this perspective would suggest that associations are based on social and economic interests, which in turn give rise not only to a stratification order due to differential capacities and influence, but also to cooperation and conflict according to these pursuits. Based on differing relations to the means of production, the German political philosopher Karl Marx (1818–1883) predicted that the bourgeoisie would protect its economic interests by repressive laws. This would create a class consciousness; because the resolution of regional, ethnic, and other conflicts among the proletariat; lead to a unified and politically organized labor movement; and ultimately result in the overthrow of the capitalist system by revolution, to be replaced by a classless, communist society. Critics argue that class theory fails to account for the growing presence of a strong middle class, the absence of antagonistic relations between classes, the continued success of elites to set agendas, and the triumph of capitalism over socialism as an economic-political system. This criticism is not as convincing as it appears at first. On the one hand neo-Marxists are able to overcome at least part of these criticisms by emphasizing the exploitative nature of economic interactions also within the growing middle class, which, based on differential access to wealth, authority, skills, or credentials, become at once exploiters and exploited within a capitalistic system. Beyond this, systematic economic exploitations and political paternalism continue to take place based on differential access to resources between nations of differing economic development levels, social groups differentiated by ethnicity or gender, and the transfer of advantage and privilege from one generation to another. On the other hand there exist other class theories that do not share the assumptions of Marxist class structures. For example, class structure can relate to the social positions of actors as identified by their integration into the labor market. This is distinct from a social hierarchy, and usually borrows from German sociologist Max Weber's (1864–1920) notions of class. In this sense, class does not imply a single hierarchical dimension. A nonhierarchical class schema as developed by, for instance, British sociologist John Goldthorpe and his colleagues, differs from class schemata based on some vertical (i.e., ascending/descending) dimension. For example, skilled industrial workers, small proprietors, and minor officials may occupy a similar position in a hierarchy, but may be separated by class in that they are subjected to very different technical and economic realities due to innovations or governmental policies. A second Weberian approach to institutional structures consists of his distinction between different authority-types: traditional, legitimated by heredity and traditions; charismatic, based on inspirational leaders; and legal-rational, based on law and rationality.

Another important tradition from an institutional perspective relates to the subjective assessment of status or prestige. The ranking or rating of occupations according to their subjectively perceived prestige and its resulting access to social, economic, and political resources started most likely with American educator George S. Counts (1889–1974) in the 1920s but was popularized by the National Opinion Research Center (NORC) in the 1940s. While some argue that it is the subjectively attributed qualities to these titles themselves that structure soci-
ety, and while others suggest that subjective aspects are merely proxies for an underlying social and economic structure, Weber emphasized the interdependence between class, status, and prestige. According to Weber power has different bases that interact with each other: class based on economics, status based on prestige and honor, and party based on political power and domination via associations. An important variant to this theme was presented by the French sociologist Pierre Bourdieu (1930–2002), who explored the convertibility between economic, cultural, social, and symbolic capital.

POLITICAL STRATIFICATION FROM A RELATIONAL PERSPECTIVE

From a relational perspective political inequality structures emerge from differentiated interactions between agents. At the base are actors such as individuals, political bodies, associations, and nation-states, which interact with each other. These interactions are patterned not only according to institutionalized rules but such interactions, never a perfect reproduction of institutional blueprints, also create, maintain, and transmute these rules. Societal structures from this perspective are based on and created from the recurring patterns of relations. Based in part on the study of religious and political characteristics of groups, German philosopher and sociologist Georg Simmel (1858–1918) proposed that society exists only as social representations, or collective ideas, which provide the basis for social relations as societies’ external form (i.e., rejecting the idea of society as something that can have a substantive existence). Indeed, the objectification of the church or the state is created from complex relations and interactions among the members of large, heterogeneous groups. In this vein democratization and social equality can be understood as the reduction of systematic power differences between group members within a social system, while the distribution of power also gives rise to the structuring of social relations in terms of cooperation, conflict, and competition. Differential relations between agents within a social system were initially studied with simple sociograms in order to understand power structures and relations. These have been replaced by more sophisticated forms of network analysis, in which power structures are explored in terms of differing relations between nodes and their quality, reciprocity, density, intensity, and durability within a network structure. This approach can be found in studies focusing on cliques, associations, interest groups, and elites.

POLITICAL STRATIFICATION FROM AN EMBODIED PERSPECTIVE

From an embodied perspective political stratification can be understood in a number of different ways. Here individuals are at the forefront as they, through continuous acts of self-definition, interpret and make sense of norms and values, and as they interact with each other. Based on the symbolic interactionist perspective of American philosopher and social psychologist George Herbert Mead (1863–1931), the “socio-physiology” of individuals underpins self-awareness, interactions, and behavior. Interactions and the thus-derived structures are based on the interpretation and internalization of rules by individuals. Or structures and stratification are based on interaction according to a system of rules, yet these interactions concurrently reproduce and transform the rules and thus the underlying structures. For French philosopher Michel Foucault (1926–1984), organizations and institutions (e.g., schools, asylums, medicine) are invested within individual bodies through discipline and punishment of their bodily activities. As such, individuals in modern societies no longer require the policing of their thoughts and activities by others but become their own guards. Connected to this notion is governmentality, which also plays a role in conceptualizing political stratification from a poststructural perspective. Governmentality refers to power as tactical and continuous negotiations between actors and institutions (e.g., markets). Meaning and knowledge are shaped via the interconnection between discursive strategies and practices. From this perspective, power is omnipresent and embedded in all forms of discourse and actions. Knowledge thus produced and internalized has the power to regulate and discipline the self. Also, Bourdieu’s notion of different forms of capital could be understood as part of embodied structures because such capitals are connected to personal fields of power and the habitus of the individual.

In sum, political structures can be conceived of in terms of institutions, relations, and bodies, although these perspectives are best understood as ways to organize different theoretical approaches rather than implying differences in kind. Throughout, controversies about political stratification center on questions such as: What is stratified? How is it stratified? What causes such stratification? And, what are its consequences? Postmodern, particularly poststructural, theorists would argue that due to technological innovations and the increased speed and efficiency of mobility of information, goods, and people, all social, economic, political, and cultural structures are dissolving. In the absence of dominant political structures and social order, individuals no longer have positions and trajectories but are either encouraged or forced to construct themselves and to interpret their environment according to context-dependent, ephemeral, media-dominated, lifestyle and consumption choices.

Such suggestions may point at important dynamics associated with modernization and globalization, but empirical evidence continues to illustrate the persistence
of structures. Part of the criticisms against structural approaches is based on three misunderstandings: inability for (privileged) individuals to perceive the constraints of structures, structures as something static, and determinacy of structures. However, individuals’ subjective experience of structures is not necessary for structures to exist. Structures do not necessary imply stability as even highly dynamic and changing systems can be based on structures. And the presence and influence of structures rarely determines completely the thoughts and actions of individuals. Despite the demonstrable social, economic, and political changes that modern (and all other societies) are experiencing, structures themselves continue to exist as they persist, adapt, or transmute. Modern questions about political structures should not be based on whether they exist but rather in what form and in which context they exist.

STREAM OF CONSCIOUSNESS

The science of psychology in large part investigates the activities of individuals and groups as they function in a social system. Many social scientists share the conviction that a psychological understanding requires not only systematic observation of behavior that occurs in a social context but also study of the mental life of the individuals involved. Human beings have access of a direct kind to part of their mental life. They are normally in a position to communicate to others a great deal of firsthand information concerning that part. Specifically they apprehend their own stream of consciousness as it is proceeding within them. William James (1842–1910) is one of the original creators of the science of psychology and is famous for the perspicacious account presented on the stream of consciousness in his masterwork *The Principles of Psychology* (1950 [1890]). The following is from James’s *Talks to Teachers on Psychology: And to Students on Some of Life’s Ideals* (1916 [1899]) and encapsulates his concept of the stream of consciousness:

Now the immediate fact which psychology, the science of mind, has to study is also the most general fact. It is the fact that in each of us, when awake (and often when asleep), *some kind of consciousness is always going on*. There is a stream, a succession of states, or waves, or fields, (or of whatever you wish to call them), of knowledge, of feeling, of desire, of deliberation, etc., that constantly pass and repass, and that constitute our inner life. The existence of this stream is the primal fact, the nature and origin of it form the essential problem, of our science. (p. 15)

I spell out here James’s concept of the stream of consciousness (cf. Natsoulas 1999, 2001) using interchangeably the terms *state of consciousness* and *consciousness state* for the basic durational components that James proposes to constitute the stream of consciousness one at a time in tight succession.

A consciousness state is generally an awareness of a number of items. It is no less an integral state given the number of its “objects.” These include states of consciousness as well as, for example, environmental properties and bodily aspects of the individual. A highly recurrent feature of the mental life of humans is the direct apprehension of states of consciousness as they occur. James holds that this “inner awareness” is a matter of one consciousness state’s having another consciousness state belonging to the same stream among its objects. It is impossible for a state of consciousness to be itself among the items it directly apprehends. James insists on the latter point notwithstanding his equally central thesis that a consciousness state commonly has many distinct objects. Not every consciousness state is an object of inner awareness. But such a state transpiring unbeknownst is no less a basic durational component of its stream. A sincere report of one’s being unaware of *x* does not on its own entail that one did not experience a state of consciousness with *x* among its objects.
A stream of consciousness consists of momentary states of consciousness one after another in a series that subjectively seems tightly adjacent. Inner awareness does not detect any interruption in the flow of consciousness however long or brief it may be. Such a stoppage must subsequently be inferred to have taken place if it is to be known of at all. Some of James’s remarks suggest that the stream of consciousness is continuous in the sense of expanding in the dimension of time through internal growth rather than by a series of external accretions. But I argue at length elsewhere that his more consistent view is that pulses of change in the brain yield pulses of mentality (Natsoulas 1992–1993). The latter series is proposed to be continuous. Each state directly follows upon the consciousness state right before it “with absolutely nothing in between” just as long as no “time-gap” intervenes. Such time-gaps do happen, according to James, owing to what is taking place in the brain. But they are not noticeable because consciousness totally ceases during any time-gap. In The Principles of Psychology James advances a dualist interactionist theory as to the relation of the mental to the physical (cf. Natsoulas, 2005). The brain generates the consciousness states, but they can in turn influence the ongoing physical process that produces them and thus indirectly affect the course that the stream of consciousness is taking. Yet no state constituting the stream is a state of the brain. Nor is any state of consciousness any kind of feature belonging intrinsically to the brain itself.

One’s consciousness is at any moment comprised completely of a single consciousness state. This is James’s (1950 [1890]) view with one exception. In the same individual a second consciousness may simultaneously flow, consisting of its own distinct states of consciousness (cf. James 1982 [1902]). Yet every state of consciousness is integral in the sense that each one of them is a unitary awareness, albeit usually possessing many objects but never compounded of distinct mental experiences or mental acts. James describes the individual complexity of the large majority of human states of consciousness (calling them “fields” and “states” interchangeably):

The concrete fields are always complex. They contain sensations of our bodies and of the objects around us, memories of past experiences and thoughts of distant things, feelings of satisfaction and dissatisfaction, desires and aversions, and other emotional conditions, together with determinations of the will, in every variety and permutation and combination. In most of our concrete states of consciousness all these different classes of ingredients are found simultaneously present to some degree, though the relative proportion they bear to one another is very shifting. (1916 [1899], p. 17)

One should not understand these many ingredients of James’s consciousness states to be separate mental acts as traditionally conceived of. They are not mutually distinct cases of someone’s being aware of something. Any object of a state of consciousness is apprehended therein in relation to all other objects of that consciousness state. James’s ingredients of the states of consciousness are (1) abstractions from individual concrete states that have them among their features, (2) features of how a consciousness state’s multiple objects are apprehended altogether, and (3) nonexistent except in the form of features of states of consciousness. Thus an auditory or a visual experience does not exist except as an ingredient of one or more consciousness states (cf. Natsoulas 2001).

From James’s standpoint references to someone’s being aware of this or that is very likely to be misleading. It is not meant to imply that the experiential features of consciousness states have a subject or an ego who is aware. This is not to say that a stream of consciousness and all of the consciousness states involved are not someone’s. Rather it is to maintain that the consciousness states themselves are the only location that there is of consciousness. Neither the brain nor any kind of spiritual entity is what experiences, thinks, feels, apprehends, or issues one’s states of consciousness and is in that sense the source or agent of one’s mental life. One’s brain does indeed bring one’s states of consciousness into existence, but it is aware of nothing at all including its doing so and the states it produces. James distinguishes the material self, the social self, and the spiritual self but identifies the spiritual self concretely with the stream of consciousness and not with any entity or operation external to the stream that causes it to be as it is or that oversees it or puts it to use. “The passing Thought [i.e., state of consciousness] itself is the only verifiable thinker” (James 1950 [1890], p. 346). It is states of consciousness in themselves that provide mental life with subjective temporal unity. They do so by appropriating immediately past consciousness states that are now objects of inner awareness and more distant consciousness states that are currently objects of remembrance.

Is James’s understanding of the consciousness states consistent with its seeming firsthand that consciousness is a “fighter for ends”? That a state of consciousness has a certain goal or type of goal among its objects is owed directly to the brain state responsible for the consciousness state’s occurrence. The influence of past states of consciousness is limited to their having reinforced or inhibited (furthered or checked) the ongoing brain process and thereby affected the course it was taking. A state of consciousness and its successors may come to intend some new goal but not as a consequence of their effects on how the ongoing brain process is proceeding. James asserts that a consciousness state can produce nothing absolutely new. But a consciousness state can help to maintain a certain

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 171
goal as an object of the stream at the expense of alternative goals and to increase thereby the chance of related actions since the brain process determines such actions and is suitably affected.

Is the stream of consciousness illusory? James (1950 [1890]) raises this question himself as he discusses the spiritual self and concretely identifies the spiritual self to be no other than the stream of consciousness itself. From certain of his own introspective efforts James surmises that all one can know of oneself in an immediate rather than an inferential way is objective (e.g., bodily states) and requires perceptual observation. Consciousness states and the streams of which they are parts are not directly apprehended and therefore are inferred constructs. James sets this skeptical position aside for practical reasons and continues to use the deliverances of inner awareness as though he has no doubts. The following questions indicate what I believe is a better reason for his going on just as he does. How can James be aware of observing x if he has no inner awareness of any state of consciousness with x among its objects? Can James tell he is observing x by making behavioral observations? Would a certain piece of James’s behavior give away to him or to others that he is observing x? But then how can anyone be aware of observing a piece of James’s behavior if there cannot occur in anyone inner awareness of any consciousness state having that piece of behavior among its objects?

**STREET CULTURE**

A primary issue for urban sociologists is the disproportionate poverty in ghettos, defined as parts of American cities that are composed of mostly poor African Americans. These economically and socially alienated communities often suffer from high rates of unemployment, crime, and drug use, creating images of these areas and their occupants that mask differences among residents and the structural conditions that affect them. Several studies have attempted to disentangle these issues by identifying systematic inequalities and the ways inner-city residents respond to them. Many note the integral role of street cultures in such neighborhoods, which help disadvantaged residents to cope with inner-city life by offering alternative methods for attaining social order.

In his 1999 ethnography, *Code of the Street*, Elijah Anderson argued that the problems of poor, inner-city black communities are exacerbated by deindustrialization, the outsourcing of jobs, the flight of the middle class, an ineffective law enforcement system, and a prominent underground economy. Anderson argued that these structural changes and the alienation they breed promote an oppositional culture whereby inner-city residents rely on the code of the street, or “a set of informal rules governing interpersonal public behavior, particularly violence” (p. 33) to distribute respect and ensure order. While this code provides residents with a mechanism to organize the community, its success relies on the use of violence to gain social status, creating a culture where the paths to money and respect reflect deviant lifestyles.

Anderson argued that within these neighborhoods, knowledge of the code becomes necessary for all individuals to maintain respect and ensure survival. Familiarity with the code holds whether individuals self-identify as decent individuals, or those who tend to hold mainstream values, or street individuals, or those who embrace and enforce the code and its use of violence. This requires decent people who do not fully embrace the code to be streetwise, or to engage the code to gain respect and to prevent challenges to their person or status. This may require individuals to challenge someone else’s power by taking that person’s belongings or through physical attack or to display material possessions, which suggests that they not only have money but also that they are willing to defend it. Such issues are particularly salient for adolescents who must negotiate their identities within public spaces, making them vulnerable to stereotyping by people who live outside these neighborhoods and who are unable to distinguish between residents who engage the code only when necessary and those who always live by it.

As an oppositional culture, the code of the street also has implications for cultural forms created in urban spaces such as hip-hop and rap music. As Mark Anthony Neal
suggested in his 2004 article, “Up from Hustling: Power, Plantations, and the Hip-Hop Mogul,” in its onset, hip-hop and rap music offered a critical voice capable of accurately portraying the black urban experience and affecting social change within these impoverished neighborhoods. Over time, however, these musical forms have been transformed into a mainstream and stylized version of black culture that no longer resembles the ghetto public it sought to represent. Neal suggested that, “what is bought and sold in the open market of commodified blackness is anything but authentic, but rather stylized perceptions of black life, packaged for mass consumption” (p. 166). This hip-hop image, which glorifies excessive consumerism, the underground drug economy, and misogynistic practices, fails to affect social change in the ways originally envisioned by hip-hop artists. Instead, these images influence public policies aimed at monitoring black urban youth, providing justifications for further discrimination against impoverished inner-city residents and legitimizing the oppositional culture posed by the code.

While previous works, such as Elliot Liebow’s 1967 ethnography, Tally’s Corner, have reached similar conclusions to Anderson’s thesis regarding the role of the street corner in redefining limited life chances, they have also been critiqued for their emphasis on oppositional culture, which suggests that in certain ways, poor, inner-city blacks contribute to their own blocked mobility. Many urban researchers have reached alternative conclusions in studies of inner-city black communities, suggesting instead that street cultures are integral resources used by disadvantaged residents to enhance their abilities to achieve middle-class status. For instance, in his 1980 book, Alley Life in Washington, James Borchert wrote that, following the Civil War (1861–1865), alley residents developed invaluable community networks that allowed them to survive through periods of intense urbanization and institutionalized racism. These ideas have also been noted in international works such as Steve Hall, Simon Winlow, and Craig Ancrum’s 2005 article, “Radgies, Gangstas, and Mugs: Imaginary Criminal Identities in the Twilight of the Pseudo-Pacification Process.” In their study of British, lower-class males, they found that these individuals do not engage in violence and criminality to resist normalization, but instead, to enhance their life chances. Studies such as these suggest that while street cultures have formed in various times and spaces, they do not always exhibit subcultural or oppositional characteristics, providing opportunities for further research that delineates the structural, spatial, and individual relations between street cultures and mainstream values.

STRESS
Stress is often used to describe overwhelming or threatening situations or the pressure that human beings encounter when experiencing such circumstances. The American physiologist Walter Cannon introduced the term stress in 1929 as an acute emergency reaction that could help the organism mobilize energy for fight-or-flight responses in dangerous situations. In 1936, the Austrian-born Canadian endocrinologist Hans Selye first used the term stress when describing threatening conditions capable of producing chronic changes in the homeostatic balance of an organism if lasting long enough. It is now known that stress and stressor exposure can elicit a complex array of physiological changes. Stress can be physical or psychological, controllable or uncontrollable, acute or chronic, and the word stress is often used imprecisely referring either to a stressor or a stress response.

Originally, the main stressors for human beings related to physical injury, predators, and starvation. Acute physical stressors required emergency reactions helping the organism mobilize energy for fight-or-flight responses, that is, physiological reactions that prepare an individual for the strenuous efforts required by fighting or running away. Threatening situations usually call for vigorous activity, and the autonomic and endocrine responses that accompany them help mobilize the body’s energy responses. During emergencies, the sympathetic branch of the autonomic nervous system is activated to help mediate arousal, activation, and mobilization. The activated sympathetic nervous system speeds up the heart rate and
diverts blood flow to the muscles, and the adrenal glands release epinephrine.

This type of acute mobilization of biological resources is clearly advantageous during short-term physical emergencies. In the contemporary world, however, people often react in this acute manner to stressor exposure that does not involve life-endangering situations. When encountering psychological or social stressors, the same physiological responses may be activated, which is likely not adaptive or appropriate. For example, the acute stress response can occur in relation to academic exams, traffic jams, relationship breakups, family feuds, or simply worrisome situations. Such activations are likely harmless in the short term but can potentially be harmful when chronically provoked. Physiological reactions to stressor exposure are also often accompanied by psychological reactions such as anxiety, worry, anger, inability to relax, and poor concentration, which again may be harmless in the short term but potentially detrimental in the long run.

**SOURCES OF STRESS**

The sources of stress can be infinite. Research has often focused on major life events, job-related stress, daily hassles, environmental stress, and sociocultural factors as sources of stress, among others. Major life events such as changing careers, getting married, or losing a loved one can entail a serious challenge. Such events luckily rarely occur, but everyday hassles such as having car trouble, getting to work late, missing a deadline, or having to run in order to catch the bus can obviously happen more frequently. Environmental stress such as pollution, noise, or natural disasters can also take its toll on people, as can job-related stress such as an unhappy boss, a manipulating co-worker, or simply a stressful and demanding working environment.

Because of evidence that stress responses are specific and may vary based on how a particular stressor is perceived, researchers have proposed models highlighting the interaction of biological and psychological factors in health and illness. One such model, the diathesis-stress model, proposes that two continuously interacting factors jointly determine an individual's susceptibility to stress and illness. One factor involves predisposing (diathesis) factors establishing a person's vulnerability to illness, for example, genetic vulnerability, and the other involves precipitating factors from the environment, such as traumatic experiences. The diathesis-stress model highlights the fact that different people have different vulnerabilities, resulting in possible health consequences because of stress combined with diathesis. Other models have proposed that how people perceive themselves and the stressor at hand may impact how they react mentally as well as physiologically when exposed to stressors. For example, if a stressor is perceived as a serious threat, this will elicit more complex reactions than if the stressor is perceived as a daily event. Another model, the stress-buffering model, posits that certain factors, such as individual differences or social support, may protect, or “buffer,” people from the impact of stressful events. In this model, individuals under stress with little or no social support, for example, experience negative health effects, whereas the negative effects of stress for individuals with high levels of social support are reduced or eliminated. Clearly, a number of factors can affect how people perceive and react to stressor exposure.

**IMPACT ON HEALTH**

Stressors are part of daily life. However, when energy is constantly mobilized at the cost of energy storage, one can never store any surplus energy. If stressor exposure is long term or overtaxes coping resources, stress can have adverse impact on health. For example, the long-term effects of prolonged secretion of glucocorticoids have been shown to involve increased blood pressure, damage to muscle tissue, growth inhibition, and suppression of the immune system. Research has also found links between stressor exposure and physiological health issues such as heart disease and cancer. This is not to say that stress causes heart disease or cancer; it is possible, however, that prolonged stressor exposure may be a contributing factor in the development of a number of physiological problems. Research has also found an effect on wound healing: Studies have found, for example, that stressor exposure can slow the healing of wounds significantly (Glaser et al. 1999), which supports the hypothesis that prolonged stressor exposure may suppress the immune system.

Stressor exposure may also contribute to psychological disorders such as post-traumatic stress disorder (PTSD). PTSD is caused by exposure to a situation of extreme danger and stress, such as acts of war, assault, injury, death of a loved one, and so on. Symptoms of PTSD include recurrent dreams or recollections, and the disorder can interfere with social activities and produce a feeling of hopelessness. Research has also indicated a link between stress and depression, as stress and glucocorticoids appear to be intertwined with the biology of depression. Sympathetic arousal is a relative marker of anxiety and vigilance, while heavy secretion of glucocorticoids is more a marker of depression, and statistically, people who are undergoing significant life stressors are more likely to become depressed, and people who are depressed are more likely to have undergone a recent significant stressor. Symptoms of PTSD as well as depression are often treated with medication to adjust the serotonin and/or epinephrine systems, either alone or in combination with some form of psychotherapy. PTSD and depression can also be treated with some form of psychotherapy alone.
Despite the impact that stressors can have on health, research has not established a clear connection between stressor exposure and health-related issues. In fact, when exposed to the same type of stressor, one person might get sick while another will not. Apparently, stress and the consequences of stress may arise from how people appraise the events rather than from the events themselves. How people appraise and cope with stressor exposure may again depend on factors such as individual differences, coping styles, perception of control, and social support. Individual differences such as dispositional optimism and explanatory style have been linked to better psychological and physiological adjustment to stressors. Dispositional optimists generally expect positive outcomes in life, while explanatory style refers to a person’s general propensity to always attribute outcomes either to positive or negative causes. A person’s resilience may also impact how stressors are perceived and met. Resiliency often refers to a person’s ability to develop coping strategies despite being in a difficult situation or the ability to bounce back when bad things happen. In general, it appears that people who see stressors as challenges to be overcome rather than insurmountable problems tend to cope with stressors in the most adaptive way.

COPING STYLES AND STRATEGIES
Coping usually refers to the cognitive, behavioral, or emotional way that people deal with stressful situations and is seen as a dynamic process involving a series of responses entailing the interaction of a person and the environment. In general, coping styles that approach the problem in order to deal with it have been found to be more adaptive than coping styles avoiding the problem. People with a strong sense of personal control are also more likely to engage in adaptive problem-focused coping. Personal control is the belief that people make their own decisions and also that an individual determines what others do to that person or what the person does him- or herself. The opportunity to control aversive events or the belief that aversive events can be controlled may play a crucial role in determining how a person might react during stressor exposure.

The degrees of social support people receive or perceive may also play an important role in how people cope with stressors. Social support is the companionship of others and the emotional or practical support of others. Research has shown social support to be important for faster recovery and fewer medical complications from surgery or illness, for lower mortality rates, for less distress in the face of terminal illness, and for reduced vulnerability to illness and mortality. It appears that people’s outcome expectancies, their coping strategies, their sense of control, and their perceived or actual social support act as factors in how they appraise stressors or as buffers against the impact of the stressor exposure.

Stress appears to be an unavoidable part of life in the contemporary world. Stressor exposure is not necessarily harmful; nevertheless, depending on the characteristics of the stressor, the length of exposure, individual differences, and coping strategies, stressors may have adverse physiological and psychological impacts on a person’s life.

Lise Solberg Nes
serves as an insulating factor, or buffer, between the stressors and the disease outcome, so that people who have more resources are less affected by stress.

Stress is typically measured by the number of major negative events that a person has experienced in the past year. These include events such as loss of a loved one or experiencing severe financial difficulty. Job strains, in an occupation in which demands are high but control is low, can serve as a stressor, and criminal victimization (assault or theft) can be quite distressing. High levels of stress have been linked to anxiety, depression, and physical health problems in studies of general populations, but buffering resources can reduce the relation between stress and disease.

One type of stress-buffering agent is social support. Social support can be defined as resources provided by others that help a person to cope better with problems. Research has shown that persons with more social support are less affected (or unaffected) by negative life events. Supportive relationships contribute to well-being because they provide a source of intimacy, acceptance, and confiding about emotions (emotional support), which provides buffering effects across a broad range of life stressors. Supportive persons may also offer useful advice and guidance (informational support). By providing such resources, personal relationships help to reduce the impact of stress on depression and anxiety. Some studies have also suggested that social support can provide buffering effects that reduce the risk of mortality from cardiovascular disease or cancer.

Personality characteristics also may serve as a stress-buffering resource. For example, a personality complex termed hardiness has been found to provide buffering effects. Hardiness is defined as scoring high on attributes of commitment (being involved with other people rather than detached or alienated), control (taking control over one’s decisions and actions, rather than passivity and powerlessness), and challenge (the ability to tolerate uncertainty and see life events as a challenge rather than a threat). Persons who score higher on hardiness show less illness at high levels of stress, compared with persons low on hardiness. Thus individuals who score higher on this personality complex are more resistant to stress.

An implication of the stress-buffering model is that interventions to enhance available social support or to teach persons positive attitudes about commitment, control, and challenge can help make persons less vulnerable to negative events. Such interventions can be conducted in school, clinic, or community settings so as to improve people’s coping ability and thereby improve the mental and physical health of the population.

STRUCTURAL ADJUSTMENT
Developing or emerging market economies may face periods of severe economic instability. This may involve a stagnant or declining economy, perhaps accompanied by high rates of inflation, a falling currency, and unsustainable foreign debt obligations. In these circumstances and often as a last resort, member countries may look for financial support from the world’s two main multilateral aid and financial institutions, the World Bank and the International Monetary Fund (IMF).

Financial support from these institutions often requires the successful negotiation of a structural adjustment loan (SAL) with the member country. These loan programs link disbursements of funds to the meeting of specified conditions (performance criteria) through the implementation of a combination of economic policy reform measures. The International Monetary Fund allows member countries to borrow, subject to agreed-upon conditions, on their economic policies. The IMF
has always had conditions on their loans, but since 1982 the number of these loans has expanded. Similarly, the World Bank pays a great deal of attention to helping countries improve their economic policies. In 1980 the World Bank began to make structural adjustment loans that carried conditions on economic policies—so-called adjustment lending. A significant part of its lending was for structural adjustment, namely loans to support reforms rather than specific investments.

The IMF and World Bank made 958 adjustment loans to developing countries between 1980 and 1998. Argentina alone was the recipient of thirty adjustment loans during this period. While these loans are often negotiated in the context of economic crisis and attempt to restore balance of payments viability and macroeconomic stability, they are geared to increasing international competitiveness and improving economic efficiency in the use of domestic resources—the term Washington Consensus is often associated with this reform package.

Often the country in crisis faces considerable economic turmoil and may have no option but to accept painful economic remedies in order to receive external funding. This may involve a menu of higher interest rates, government spending cuts and higher taxes, and the abolition of various subsidies on consumption items. These policies are unlikely to be popular, and so the programs are extremely controversial. The SALs often include trade liberalization measures that place fewer restrictions on foreign trade. These measures include reducing or abolishing tariffs and quotas on imports, a less restrictive stance toward foreign investment, a more realistic exchange rate, and capital account liberalization that reduces controls on capital flows across national boundaries. The internal market-oriented structural reforms promote deregulation of domestic markets and the privatization of government enterprises.

THE EFFECTIVENESS OF STRUCTURAL ADJUSTMENT PROGRAMS

Restoring macroeconomic stability in times of crisis is critical. Indeed the ability to restore and maintain macroeconomic stability in the face of often-turbulent external conditions is one of the most important factors accounting for the diversity of economic performance in the developing world. The effectiveness of SALs in achieving this objective is a hotly debated issue. In his 2001 book, The Elusive Quest for Growth, William Easterly notes that

“In the 1980s, the World Bank and the IMF gave an average of six adjustment loans to each country in Africa, an average of five adjustment loans to each country in Latin America, an average of four adjustment loans to each country in Asia, and an average of three adjustment loans to each country in Eastern Europe, North Africa and the Middle East. The operation was a success for everyone except the patient. There was much lending, little adjustment, and little growth in the 1980s and 1990s. The per capita growth rate of the typical developing country between 1980 and 1998 was zero.” (pp. 102–103)

Some studies even suggest that a higher IMF loan-participation rate reduces economic growth and conclude that the typical country would be better off economically if it committed itself not to be involved with IMF loan programs.

A number of concerns arise about the effectiveness of SALs. One issue relates to the speed of the structural adjustment required. Should all of these policies be implemented immediately or only gradually? Governments may stall in implementing the required policies, use creative financial accounting to avoid real adjustment, or reverse the policies once the program is over. A second issue relates to the sequencing of structural reforms. Many commentators point to the crucial role of foreign capital inflow during the structural reform period to reduce the frictions that will emerge during the transition. It may be preferable, however, that controls on foreign capital be relaxed only after trade and other industrial-sector distortions have been dismantled. The reason for this is that capital inflow will result in a real exchange rate appreciation that disadvantages exporters. Meanwhile, the tariff reductions will disadvantage domestic producers facing lower-priced imports.

Privatization policies as part of a SAL have also been questioned, particularly in the transitional economies of eastern Europe. Public assets may be sold off below their real value in order to find a buyer and to generate quick cash flow, with a loss of public accountability. Privatization might also mean that income-generating assets are sold, leaving behind all the residual “unproductive” activities, plus a new layer of watchdog agencies to regulate the newly privatized activities.

In the context of the 1997 Asian financial crisis, further debate escalated on the effectiveness of SALs, particularly the financial deregulation requirements. In this context the views of Joseph Stiglitz have been well publicized, particularly his stinging condemnation of the response of the IMF and the U.S. Treasury to the Asian crisis in his 2002 book, Globalization and Its Discontents. Stiglitz rails against the IMF’s “market fundamentalism,” its “one-size-fits-all” approach to crisis management, and “its mistakes in sequencing and pacing, and the failure to be sensitive to the broader social context” (p. 73). Rescue packages were overly contractionary and pushed the economies deeper into recession. Inadequate attention
was given to the social dimensions of the crisis. In particular, greater efforts were needed to ensure food security and preserve the purchasing power of vulnerable households. Finally, there was a lack of appreciation of the potential for irreversible social breakdown in the midst of economic crisis, with rising ethnic and factional violence. The impacts of SALs on social sectors and the poor have been particularly troublesome, and the IMF and World Bank have incorporated social safety nets into their programs (Cornia, Jolly, and Stewart 1987–1988).

The IMF has staunchly defended the economic policies that it recommended to the crisis-affected countries of Asia. It argues that the causes of the crisis were internal or homegrown, reflecting underlying structural distortions and macroeconomic imbalances. The use of high interest rates on a temporary basis was essential to correct the excessive competitive devaluations in the crisis countries. Insolvent financial institutions had to be closed down and belt-tightening was essential. The IMF notes that the recoveries of some of these countries point to the effectiveness of its policy advice.

One of the interesting empirical findings relating to the effectiveness of SALs is that the results often depend on the characteristics of the specific country concerned. Countries have generated a variety of responses to basically similar SALs. This seems to reflect the importance of differences in institutional, social, and historical conditions between countries (Taylor 1988).

A REASSESSMENT

The disappointing response to repeated structural adjustment lending has led to much soul searching. At the IMF, poverty reduction and growth facilities have replaced structural adjustment loans. Reducing the microeconomic interventions and concentrating on core macroeconomic concerns have streamlined conditionality. There is also now a focus on pro-poor growth and social safety nets. There was a perceived need to move beyond Washington Consensus policies to so-called second-generation reforms, following the growing recognition that market-oriented policies may be inadequate without more serious institutional transformation. The expectations placed on lending to developing countries conditional on their making policy reforms proved unrealistic. There is a growing recognition that structural adjustment should promote growth and capacity expansion and not just efficiency. The recommendation now is for a more strategic focus, concentrating on the key barriers to growth, rather than employing a scattergun approach to abolishing all market distortions.

STRUCTURAL EQUATION MODELS

Structural equation modeling (SEM) is a general method for modeling systems of effects among three or more variables. Structural equation models can vary greatly in complexity. At its base, SEM is an extension of linear regression (or, linear regression is a special case of SEM) in which a number of regression equations are solved simultaneously. This process allows for the explicit modeling of many quantities not typically a part of linear regression, including the covariances (or absence thereof) among predictors, the residual variances of the endogenous (predicted) variables, and measurement error in both the exogenous and endogenous variables.

COMPONENTS OF A STRUCTURAL EQUATION MODEL

A full structural equation model consists of a measurement part and a structural part. It is the measurement part that allows for the modeling of measurement error. As in factor analysis, the modeler typically assumes that some latent construct is measured by its influence on one or more (usually at least three, for model identification purposes) observed variables. A latent construct is some unmeasured, and perhaps unmeasurable, variable of substantive interest. In a traditional measurement model, the latent construct is established by its effects on the observed indicator variables; for example, self-esteem as a construct might be measured by several items on a questionnaire covering a range of related content. Each item is modeled as being fully determined by two quantities: the self-esteem latent construct and an item-specific residual, or disturbance, usually considered uncorrelated with the

Structural Equation Models
residuals of the other items and other variables in the model. Thus, the observed covariances among the items are fully determined by their common cause, the latent construct; alternatively, the latent construct is defined by that portion of the variance of the indicators that is in common.

**MEASUREMENT MODELS**

Such a model, with one or more latent constructs, each with its own indicators, can stand by itself as a confirmatory factor analysis (CFA). CFA is a special case of SEM. In CFA, the measurement models for the constructs of interest are estimated, and the covariances among the constructs are freely estimated; that is, there are no hypothesized constraints on relations among the latent constructs. Importantly, these covariances are estimated incorporating correction for measurement error. As the latent variable is that variance which is common among the observed indicators, the indicator-specific residual variances (error) have been removed from consideration. Many social science researchers conduct a CFA on their data before moving to a full structural equation model.

A CFA is distinct from an exploratory factor analysis (EFA) in that, for CFA, the latent constructs are conceptualized a priori, as are the patterns of relations between constructs and indicators. EFA is statistically very similar to CFA but has a different purpose. If the researcher does not have an a priori model, or, perhaps, the CFA results in a poor fit to the data, EFA might be used. In EFA, all observed indicators are modeled as having been caused by all latent constructs (of a number specified by the researcher, often based on empirical aspects of the data), with only certain identifying restrictions. In contrast, most CFAs in the social sciences model each indicator as being caused by exactly one latent construct (though there is no statistical necessity to do this), resulting in a more clear definition of the latent construct. Latent constructs in EFA can be more difficult to describe, as the description is determined by the researcher’s interpretation of the pattern of loadings (regression coefficients) relating each indicator to the construct.

**STRUCTURAL MODELS**

The second part of a full structural equation model is the structural part: the model of the relations among the latent constructs. Each construct can be modeled as having multiple effects on and/or multiple causes from other constructs. Thus, each endogenous, or downstream, construct is the outcome variable in a multiple regression equation and may well be a predictor variable in one or more multiple regression equations for other outcomes. These relations are typically represented pictorially in a diagram with directional arrows representing modeled effects, and curved, bidirectional arrows representing covariances among the exogenous variables (as in path analysis; indeed, path analysis is a special case of SEM in which there is no measurement model, for the constructs of interest are the measured variables). In most cases, all the exogenous variables are modeled with all possible correlations among them represented. A failure to include such a correlation would in effect be a hypothesis that that correlation equals zero, which is rarely applicable to exogenous variables. Observed variables (indicators) are usually diagrammed as labeled rectangles, latent variables as ovals.

As in the measurement part, residual variance is explicitly modeled. In all but rare cases, each endogenous variable has an exogenous disturbance associated with it—a latent variable that is the “cause” (actually the pooled causes) of all variance not determined by the regression relations.

**MODEL ESTIMATION**

When the full model has been established, the next step is to estimate the coefficients for each covariance, effect, and loading (the measurement coefficients). Each effect and loading estimate is a partial regression coefficient: the regression of the specified endogenous variable on the specified “upstream” variable, controlling for the other variables that have effects leading to the endogenous variable. And thus the coefficients are interpretable as partial regression coefficients: the change in the downstream variable per unit change in the upstream variable, holding all other variables constant. Certain hypotheses involving the path coefficients can be tested as in regression, such as the null hypothesis that the path coefficient equals zero, which is tested by the ratio of the coefficient to its standard error.

Structural equation modeling software routinely calculates a number of indices of fit of the model. A fitted model allows for the calculation, from the various path coefficients and estimated variances, covariances, and residual covariances, of a model-implied variance/covariance matrix of the original variables—that is, a covariance matrix that is consistent with the fitted model. Broadly speaking, the fit of the model is an assessment of how well the model, with its estimated coefficients, implies a covariance matrix that matches the original matrix from the data. If there is no significant discrepancy, as measured by a chi-squared statistic, then it may be concluded that the path model is consistent with the data. Note that this does not necessarily indicate that the model is an accurate depiction of causation in reality, but only that it is not inconsistent with reality as indicated by the covariance matrix.
There has been, however, much debate over the utility of the chi-squared statistic. It is widely agreed that, assuming an adequate sample size, a nonsignificant chi-square results in a failure to reject the model. However, there may be cases where the chi-squared statistic is sensitive to small deviations between the actual and implied covariance matrices that are not of practical importance to the researcher; this is especially true when the sample size is large. As a result, numerous statistics have been developed to assess approximate or close fit. Among the more prominent of these are the comparative fit index, the Tucker-Lewis index, and the root mean squared error of approximation.

**HYPOTHESIS TESTING**

The test of model fit is one of the primary results of estimating a model. Other hypotheses of interest in SEM frequently involve constraints on the structural coefficients; for example, that two coefficients are equal to each other, or that a set of three coefficients are all equal to zero. These can readily be tested in structural equation modeling software by the estimation of nested models. In this situation, the fit of a full model (without the constraints) is compared with a restricted model (with the constraints applied in the estimation process). Two such models are nested if the restricted model can be created strictly by imposing constraints on the full model. If the full model fits the data well, then the difference between the chi-squared statistics for the two models is itself distributed as a chi-squared statistic, with degrees of freedom equal to the number of constraints applied. A significant chi-squared statistic indicates that the restricted model fits significantly less well than the full model.

**STRUCTURAL TRANSFORMATION**

There is considerable debate across and even within theoretical perspectives and social science disciplines as to the nature of “social structures.” Nonetheless, there is also general consensus that structures are more or less fixed aspects of social life that cannot be significantly altered by isolated actions. The division of labor, modes of production, state institutions, and even aspects of symbolic culture, such as language, can all be seen as structures that individuals face as fixed, stable, and resistant to change. Nonetheless, as William Sewell (1992), among others, has pointed out, too often social-scientific notions of structure reify such social forms, implying their domination of agency and their imperviousness to change. Permanent and unmov ing as they may seem from any given time or vantage point, structures are far from immutable. Instances of macrosocial change in the foundations or basic architecture of any given social form, and in the patterns of agency associated with that form, are often referred to as structural transformations. The term is too widely and loosely used in the social sciences to give it a precise, comprehensive meaning, but it is possible to speak of some prevalent usages.

Perhaps most famously, Jürgen Habermas wrote of the “structural transformation of the public sphere.” Habermas identifies a moment in the histories of Britain, France, and Germany in which there developed public arenas for rational political debate (at least among middle-class men) within emerging democratic cultures. These arenas effectively mediated between private life and the state, cultivating both critical rational discourse among participants and a forum for ideas and debate as to how democratic governance could be achieved. Habermas identifies several key social processes that undermined and transformed the public sphere into something quite different, including the tremendous growth in the size and scale of the public sphere that accompanied democratization, the blurring of the lines between private and public that accompanied the growth of the welfare state, and the development of political parties, professionalized politicians, and a mass media oriented toward marketing rather than public debate.

Habermas’s work on the public sphere has sparked a lively literature on the nature of democratic processes, rational discourse, and communication in modern societies. Among others influenced by Habermas, for example, Craig Calhoun (2006) has argued that higher education is currently undergoing a structural transformation characterized by skyrocketing costs, the marginalization of teaching, and the shift in focus from public goods production to private goods distribution, with dramatic consequences for the role of higher educational institu-
tions in the economy and public life. Calhoun identifies three key processes fostering this transformation: (1) the massive increase in the size and scope of universities, which has, among other things, intensified status-driven enrollment competition; (2) declining public funding; and (3) related trends toward privatization, most obviously in the rapidly intensifying pursuit of intellectual property revenues.

In addition to Habermas’s and Calhoun’s identification of rapid increases in social scale (we might also include Max Weber’s account of the rise of bureaucratic organization as a transformative response to this problem of size), other key processes seen as primary contributors to structural transformations involve the intermixing of different kinds of people and the development of new modes of economic, political, and cultural activity. Contemporary observers may connect such social changes to globalization, but of course this is not a uniquely modern phenomenon. Anthropologists speak of the structural transformation of linguistic communities (Silverstein 1998) and hunter-gatherer institutions (Riches 1995) as sometimes wrought by confrontations of new peoples in contexts of exploration, migration, and war.

Economists, of course, are most closely associated with the transformations of economic structures. Used in this context, the term is most often understood to involve the change from one sort of economic production system to another, perhaps most prominently the change from an agriculturally based economy to an industrial one or from a nonmarket to a market-based economy (Johnston 1970; Gollin et al. 2002). The processes involved in such shifts are too numerous, complex, and contested to be discussed here, potentially arising from a host of economic (e.g., the rise of national and international markets, the influence of the International Monetary Fund), political (e.g., elections, revolutions, and wars), and cultural factors (e.g., the rise of the “Protestant ethic”). Nonetheless, such changes, as with other sorts of structural transformations, are commonly seen as having massive consequences for the societies and individuals experiencing them, not the least of which are a fundamentally altered division of labor and the social mobility system. Out of such transformations, new patterns of social relations and social forms arise that condition social action in various but profound ways.

**Structuralism**

Structuralism is the theoretical position that finds meaning in the relation between things, rather than in things in isolation. In other words, it gives primacy to pattern over substance. To take a crude example, the colors red, green, and amber take on the meanings “stop,” “go,” and “caution” in relation to each other, in the context of a traffic light. In some other context, and in opposition to other colors, red may mean something completely different, such as socialism or communism, or humanity or sacrifice. Such meanings may be either part of a universal pattern or culturally determined.

**SAUSSURE AND EARLY APPROACHES IN LINGUISTICS**

Structuralism began in linguistics and spread to anthropology, philosophy, literary criticism, and other fields. Its founder was Ferdinand de Saussure (1857–1913), a Swiss linguist who wanted to move beyond the historical interests that dominated his field in the early twentieth century. Although the work he published during his lifetime was entirely in the historical tradition, he left behind lectures given between 1906 and 1911 that set the scene for a new synchronic, structural analysis of language. These were published posthumously as the *Course in General Linguistics* (1916).

In the *Course*, Saussure made four distinctions which are now commonplace both in language studies and in many social sciences. The most important is the distinc-
tion between synchronic (at the same time) and diachronic (through time). His own interest in the (synchronic) structure of language was thus contrasted to others’ interests in the (diachronic) history of languages. The second was between langue and parole—the French words always being used for this distinction. Langue refers to “language” in the sense of linguistic structure or grammar and, by extension (e.g., later, in anthropology or sociology), to the “grammar” of a culture or society. Parole means “speech” or actual utterances of individuals and, by extension, the actual actions of individuals in a social structure. The third distinction was between syntagmatic and associative (later called paradigmatic) relations. The former are relations between words or smaller units within a sentence and, by extension, the relations between elements with a cultural “sentence” such as the traffic light sequence mentioned above. The latter marks the relation between those elements and what they mean. Finally, Saussure considered the relation between signifier (a word or symbol that stands for something) and signified (what it means), these two elements together making up what he called the sign. He stressed that the sign is arbitrary: It depends on knowing the language. In his example, if I speak French, I call the dog le chien, but if I speak German, I call him der Hund.

Later structuralists in linguistics developed Saussure’s ideas further, including, for example, the French Indo-Europeanist Émile Benveniste (1902–1976), who studied under one of Saussure’s students. Benveniste added the distinction between énoncé (a statement independent of context) and énunciation (a statement in context), the latter exemplified by the subject/object opposition of first- and second-person pronouns. This, in turn, suggested the further understanding of language as discourse.

Another major development is credited to Roman Jakobson (1896–1982), Nikolai Trubetzkoy (1890–1938), and others of the “Prague school,” active first in Prague in the 1930s and later in the United States and elsewhere. They applied Saussurian distinctions at the level of phones (sounds), which are grouped slightly differently into phonemes (meaningful units of sound) by different languages according to the presence or absence of certain distinctive features. English, for example, distinguishes the unvoiced labiodental fricative /f/ from its voiced equivalent /v/: “Fat” is a different word from “vat.” Jakobson was also important for his emphasis on the distinction between metaphor (relations of similarity, such as a crown as in the trademark of a beer company) and metonymy (relations of contiguity, such as a crown standing for sovereignty). In studies of the acquisition of language, he found that aphasics have difficulty with this aspect of language function.

In anthropology, there have been three main approaches in structuralist thought. First, the classic French structuralism of Claude Lévi-Strauss and his followers maintains a search for universal principles. In his kinship studies, for example, Lévi-Strauss sought the system of all possible systems and the structural principles that differentiate one kinship system from another: positive or negative marriage rules, marriage to one kind of cousin or another, and the effects of such marriage principles, when repeated, on relations among social units within a society. A rule of marriage of men to the category of the mother’s brother’s daughter, for example, would create a system of “generalized exchange” in which group A gives its daughters in marriage to group B, and group B to group C (not to group A). The same pattern is repeated through the generations. Marriage to the father’s sister’s daughter, however, creates a demographically unstable pattern of “delayed direct exchange” in which women marry in one direction in one generation and in the opposite direction in the next generation. The latter systems are virtually nonexistent or break down easily when created. A system that allows marriage to either of these kinds of cousin, by contrast, fosters “direct exchange” between just two groups, sometimes with men exchanging their sisters with other men.

Second, J. P. B. de Josselin de Jong (1886–1964) and his students from the 1930s onward, working mainly in the East Indies, were interested in patterns occurring within that culture area. Later scholars in Holland, Belgium, and Britain sought similar patterns elsewhere, and the idea was that each cluster of cultures had its own system, and an anthropologist could better understand a society in terms of its contrast to related cultures within that area rather than on its own. There are elements of this regional approach too in Lévi-Strauss’s work on South American Amerindian mythology.

Third, British structuralists, such as Sir Edmund Leach (1910–1989) and Rodney Needham (1923–2006), in the 1960s and 1970s emphasized relations between elements within a given culture. Both the Dutch and the British structuralists had an interest in kinship structures, which for the Dutch especially involved a search for regional patterns and large cultural associations, and for the British usually more specific ones, as, for example, in Needham’s reanalysis of symbolic associations among Purum in eastern India between wife-givers/wife-takers: superior/inferior, private/public, east/west, life/death, sacred/profane, village/forest, prosperity/famine, and moon/sun.

Much of this work, including Lévi-Strauss’s, was based on the application of Jakobson and Trubetzkoy’s notion of “distinctive features” to culture. The idea was
that the same structural principles that govern language also govern culture and that simple “binary oppositions” defined by the presence or absence of some feature were significant especially for the understanding of kinship, symbolism, and mythology. Famously, Lévi-Strauss’s work on North and South American myths, such as his four-volume *Mythologiques* (literally, “mytho-logics”), sought explanations for the meaning of myth through such simple distinctions and their transformations. Elements in mythology, such as different kinds of animals and their actions, say, one flies up, the other down, can be dissected by the structuralist, who thereby can understand the cultural code of the mythological system from the people who possess it.

**OTHER STRUCTURALISTS**

Among other structuralists were the psychoanalyst Jacques Lacan (1901–1981) and the Marxist writer Louis Althusser (1918–1990). Lacan stressed the importance of language in defining identity. He reinterpreted Sigmund Freud through Saussure, arguing that the unconscious has a structure not unlike language. Lacan emphasized opposition (e.g., love is the opposite of hate), thereby suggesting that language is never complete but implies what is left out. In a similar vein, Althusser reinterpreted Karl Marx, arguing for a deep “symptomatic” reading to move beyond the “surface” reading of his contemporaries. He suggested that one needs to understand the structure of the whole in order to explain modes of production. For Marx, he says, there is no distinct individual because the individual is embedded in the social context. Likewise, one should not see in Marx economic determinism (the Marxian base as determining the superstructure) because both the base and the superstructure are part of the same system.

At least implicitly, structuralism remains at the root of much of early twenty-first-century thinking in the social sciences, although its specific tenets are often now overshadowed by new interests and its simplistic vision attacked as misleading. It remains a touchstone even for its critics because so much in poststructuralism depends on understanding structuralist thought at its root and so much in postmodernism requires an understanding of what it is that is being rejected.

Linguists moved on from structuralism through Noam Chomsky’s work, which from the 1960s has emphasized universals over the structural features of particular languages. Yet in linguistics, phonemes and other structural elements of language, though sometimes defined differently than they were by Jakobson and Trubetzkoy, remain essential. Anthropology has decidedly moved on in several directions, and there have been interesting criticisms of structuralist thought in that field. One of the most important was that of the French anthropologist-sociologist Pierre Bourdieu (1930–2002), who attempted to break down the static notion of structure he saw in Saussure and Lévi-Strauss—dependent on oppositions such as *langue*/*parole*, as well as system/event and rule/improvisation. Bourdieu wished to emphasize individual action, not within the structure, but in what he called the *habitus* or environment of “dispositions.” The French historian of science Michel Foucault (1926–1984) had a similar impact. Early in his career, he stressed the absence of order in history and suggested that *parole* rather than *langue* is its essence. Later he came to emphasize “discourse” over structure. Again, this linguistic concept is used in a metaphorical sense, implying a way of talking about something or the body of knowledge implied. Inherent in this, as in much poststructuralist and postmodernist thinking, is a notion of power that is absent in classic structuralist concerns.

**STUDENT NONVIOLENT COORDINATING COMMITTEE**

On February 1, 1960, four black freshmen from North Carolina A & T College (now University) went to the Woolworth’s 5 and 10 cent store in downtown Greensboro, North Carolina. After shopping for a few items they proceeded directly to the store’s lunch counter, their real objective. They all took seats and were promptly
ignored. The students were not surprised by the waitress’s refusal to serve them. In fact they knew they were flirting with danger by flagrantly violating the local segregation ordinance barring African Americans from service in white restaurants, because they had recently spent several weeks talking about the options available to them to combat segregation.

The Greensboro students were not the only ones discussing protest strategies during the 1959–1960 school year. On the contrary, black students all over the South were holding discussion groups and workshops on the topic. In the days and weeks following the Greensboro sit-ins, African American students from other schools began to sit in at segregated downtown lunch counters. Adult leaders soon recognized that a full-fledged student movement had begun. One of those who appreciated the effectiveness of the fledgling student movement was longtime activist Ella Baker (1903–1986). Previously, Baker had worked with the National Association for the Advancement of Colored People (NAACP). Some time later she advocated the creation of a permanent organization in the wake of the Montgomery bus boycott in Montgomery, Alabama, resulting in the establishment of the Southern Christian Leadership Conference in 1957.

In April 1960 Baker urged student leaders to attend a conference that she planned to hold at her alma mater, Shaw College (now university) in Raleigh, North Carolina. Before the students left Raleigh they had established the Student Nonviolent Coordinating Committee (SNCC). By the spring of 1961, the young organization became involved in civil rights campaigns of national scope such as the Freedom Rides (when members of the SNCC rode interstate buses through the Deep South to test a 1960 law forbidding racial segregation in interstate transportation). By the end of the summer, two competing strategies emerged in SNCC: nonviolent direct action and voter registration. At a particularly stormy meeting in August 1961, the group decided that it would do both.

As the organization matured over the next few years, SNCC activists were involved in virtually every major campaign of the Civil Rights movement from the March on Washington in 1963 to Mississippi Freedom Summer, a voter registration campaign in African American communities in Mississippi. During these tumultuous years, the young people of SNCC did the grueling and dangerous work of confronting every aspect of segregation from black disfranchisement to black economic inequality. SNCC organizers were threatened, jailed, brutalized, and a few were even killed. Along the way some of them denounced the Vietnam War, as well. The FBI placed them under surveillance, and the organization was harassed by the IRS. After several years of working for reform in some of the most isolated areas of the rural South, some members of the organization began to rethink their position on a number of issues, including their support for integration. This critical philosophical shift soon resulted in a very public expression of support by some members of SNCC for the concept of Black Power, a political movement that sought to bolster racial consciousness among African Americans. Consequently, members of the group began to shift their focus to issues of black economic equality and black political education. As the 1960s drew to a close, SNCC members drifted to pursue individual goals. For a brief time in the late 1960s, some attempted to form an alliance with the Black Panther Party, a political organization founded to promote civil rights and self-defense, but it was short-lived, and the Student Nonviolent Coordinating Committee soon passed out of existence. But in many of the communities where SNCC worked, black people still remember and appreciate the efforts of the SNCC kids to help them organize for social change.

STUDENT’S T-STATISTIC

In measuring social and economic progression, statistical methods that take into account various magnitudes of uncertainties are used for inference and decision-making. One of the tasks in statistical inference is to estimate population mean from a sample of observations. For example, one may want to estimate the mean value of the retail price ($\mu$) of a gallon of unleaded gasoline based on prices ($X_i$’s) from a few gas stations in a large city. A natural estimate of $\mu$ is the arithmetic sample mean $\bar{X} = \sum_{i=1}^{n} X_i / n$. The estimator $\bar{X}$ has many desirable statistical properties, especially when $X_i$’s are independent and identically distributed as a normal (Gaussian) random variable with

\[ X \sim \text{Normal} \left( \mu, \sigma^2 \right) \]

where $\mu$ is the mean and $\sigma^2$ is the variance.
mean $\mu$ and variance $\sigma^2$. From properties of normal distribution, the following Z-statistic

\[ Z = \frac{\bar{X} - \mu}{\sigma / \sqrt{n}} \]

is a standard normal random variable with mean $\mu = 0$ and variance $\sigma^2 = 1$. This Z-statistic has been used to make statistical inferences and decisions when variance $\sigma^2$ is known or the number of observations $n$ is large. However, in most applications, the variance $\sigma^2$ is usually unknown and the number of observations $n$ may be small. William Sealy Gosset (1876–1937), a chemist at the brewery of Arthur Guinness Sons and Co. (Boland 1984), studied the small sample property of

\[ T = \frac{\bar{X} - \mu}{S / \sqrt{n}} \]

where $S^2 = \sum_{i=1}^{n} (X_i - \bar{X})^2 / (n - 1)$ is the sample variance. Gosset’s work resulted in the birth of Student’s T-statistic. Gosset published his work in Biometrika in 1908 under the pseudonym “Student” from his 1904 report to the company titled “The Application of the Law of Error to Work of the Brewery.” Gosset’s employer was against the work done for the company being made public but allowed him to publish it under a pseudonym. Gosset’s original statistic was

\[ \frac{\bar{X} - \mu}{\sqrt{\sum_{i=1}^{n} (X_i - \bar{X})^2 / n}}. \]

The Student’s T-statistic used in the current formulation in expression (2) is due to English statistician Ronald Aylmer Fisher (1925).

Student’s T-statistic was one of the important breakthroughs in statistical sciences in the twentieth century (Kotz and Johnson 1992). The density function of the Student’s T-statistic with $\nu$ (integer) degrees of freedom is

\[ \frac{\Gamma(\nu+1)}{\sqrt{\pi \Gamma(\nu/2)}} \left(1 + \frac{\bar{X}^2}{\nu} \right)^{-\nu+1/2}, \]

where $\Gamma(a)$ is the Gamma function defined as

\[ \Gamma(a) = \int_0^\infty x^{a-1}e^{-x}dx. \]

Density functions of the Z-statistic and Student’s T-statistic are bell-shaped curves with Student’s T having a heavier tail. The density function of Student’s T-statistic relative to the density function of the standard normal is shown in Figure 1.

The distribution of the Student’s T-statistic is the Student’s T-distribution and statistical tests based on the Student’s T-statistic form various Student’s T-tests. The expectation (mean) of the Student’s T-statistic is 0, and the variance is $\nu/(\nu - 2)$ for $\nu \geq 2$. When $\nu = 1$, the Student’s T-statistic becomes the Cauchy random variable, which does not have a variance. The Student’s T-statistic has infinite variance when $\nu = 2$. The degrees of freedom of the Student’s T-statistic defined in expression (2) are $n - 1$.

Student’s T-statistic has been used for estimation and decision-making in many fields of science ranging from agriculture, biology, economics, public health, and zoology. As a simple illustration, to estimate the average unleaded retail gasoline price per gallon in a large city, the author of this entry conducted an informal random sample survey on his way (seventeen miles) home at the end of April in 2006. He observed prices of $2.999, 2.879, 2.959, 2.839, 2.899, 3.019, 2.919, 2.859$ without the duplicates. The sample mean $\bar{X}$ of these seven observations was $2.930$. Under normality assumption of the gasoline price, the sample mean is usually a good point estimator of the underlying mean value $\mu$. Because of the randomness of the sample, a better approach for statistical inference is to construct an interval estimator. A classic method is to find the $100(1 - \alpha)\%$ confidence interval for the underlying mean gasoline price based on the Student’s T-statistic:

\[ (\bar{X} - t_{1-a/2, n-1}S/\sqrt{n}, \bar{X} + t_{1-a/2, n-1}S/\sqrt{n}), \]
Student’s T-Statistic

where \( t_{1-\alpha/2, n-1} \) is the critical value that satisfies

\[
P(|T| \geq t_{1-\alpha/2, n-1}) = \alpha
\]

and \( \alpha \) is the probability that the confidence interval does not cover the true underlying mean value \( \mu \). The critical values of Student’s T-statistic for various values of \( \alpha \) and degrees of freedom are available in all statistical software packages and in most basic statistical books. A commonly used confidence is 95% (\( \alpha = 0.05 \)) for interval estimation. From our sample observations, the 95% confidence interval for \( \mu \) is

\[
(2.930 - 2.447 \cdot 0.065/\sqrt{7}, 2.930 + 2.447 \cdot 0.065/\sqrt{7}),
\]

which is (2.870, 2.990).

In addition to estimation, Student’s T-statistic is also useful for hypothesis testing. The hypothesis to be tested is the null hypothesis. For example, the null hypothesis may be \( H_0: \mu = \mu_0 \) and the alternative hypothesis can be set as \( H_1: \mu \neq \mu_0 \) (two-sided test). One may commit two types of errors in testing statistical hypotheses. Rejecting the null hypothesis when it is true is the Type I error and accepting the null hypothesis when it is false is the Type II error. The probability of making Type I error is denoted by \( \alpha \), which is the same value used above for constructing a confidence interval. The probability of making Type II error is denoted by \( \beta \). Type I error and Type II error are inversely related. The power of the test is \( 1 - \beta \), which is the probability of rejecting the null hypothesis when it is false.

As the sample size increases, the degrees of freedom are large (\( \nu \approx \infty \)). The absolute value of the observed Student’s T-statistic converges to the standard normal random variable \( Z \). Asymptotically, one may use the \( Z \)-test to replace the Student’s T-test when degrees of freedom are large (\( n \geq 30 \)).

The above simple example on estimation and hypothesis testing is formulated based on a two-sided Student’s T-statistic. Similar estimation and hypothesis testing can be done for a one-sided test. In planning a scientific investigation, scientists need to decide how many samples are needed in order to control both Type I and Type II errors. Student’s T-statistic plays a fundamental role in designing scientific investigations. Alan Agresti and Barbara Finlay (1997) provide an introduction to statistical estimation and hypothesis testing.

Student’s T-statistic can be extended in many directions. For example, if \( X_i \) denotes the difference of the gasoline prices of a gas station at two different occasions, one can conduct a paired Student’s T-test for quantifying the changes. If one wants to make a statistical comparison of the gasoline prices in two cities, one may construct a two-sample Student’s T-statistic

\[
\frac{\bar{X}_1 - \bar{X}_2}{\sqrt{S^2_{p}}/\sqrt{n_1} + S^2_{p}/n_2},
\]

where \( n_1, n_2 \) are the number of observations from sample (city) one and two, respectively, \( \bar{X}_1 = \Sigma i=1^n X_1/n_1 \), \( \bar{X}_2 = \Sigma i=1^n X_2/n_2 \), \( S^2_{p} = \Sigma i=1^n (X_1 - \bar{X}_1)^2/(n_1 - 1) \), \( S^2_{1} = \Sigma i=1^n (X_1 - \bar{X}_1)^2/(n_1 - 1) \), \( S^2_{2} = \Sigma i=1^n (X_2 - \bar{X}_2)^2/(n_2 - 1) \). If the two samples have equal variances, one can form the pooled Student’s t-statistic as

\[
\frac{\bar{X}_1 - \bar{X}_2}{S_{p}\sqrt{1/n_1 + 1/n_2}},
\]

where

\[
S^2_{p} = \frac{(n_1 - 1) S^2_{1} + (n_2 - 1) S^2_{2}}{n_1 + n_2 - 2}
\]

is the pooled sample variance. Under the null hypothesis of equal means of \( X_1 \)'s and \( X_2 \)'s, the two-sample Student’s T-statistic in expression (7) follows the Student’s T-distribution with \( n_1 + n_2 - 2 \) degrees of freedom if \( X_1 \)'s and \( X_2 \)'s are independent and identically normally distributed.

For more advanced statistical inferences, such as in correlation analysis, linear regression, and generalized linear models, the estimators of the parameters are approximately of Student’s T-distribution. Hence, one can perform a statistical analysis on the estimated parameters based on Student’s T-statistic.

As the sample size increases, the degrees of freedom increase and the Student’s T-statistic converges to the standard normal random variable \( Z \). Asymptotically, one may use the \( Z \)-test to replace the Student’s T-test when degrees of freedom are large (\( n \geq 30 \)). Student’s T-statistic is widely used for small sample analysis. One of the fun-
damental assumptions in deriving the distribution of Student's T-statistic is the normality of X_i's. This assumption is not easy to check for a small sample size. Many nonparametric (distribution-free) procedures have been proposed for conducting statistical inference without assuming normality of X_i's (Hollander and Wolfe 1999). For multiple sample inferences, Fisher (1925) extended the two-sample Student's T-test to analysis of variance (ANOVA) when X_i's are normally distributed. Without assuming normality, many rank-based techniques were developed for nonparametric versions of the two-sample Student's T-test and Fisher's ANOVA (Hollander and Wolfe 1999). A great many statistical methods have been invented in the twentieth century. Student's T-statistic is one of the most widely used statistical tools not only by professional statisticians but also by all scientists involved in data analysis and decision making.

STUNTED GROWTH

Linear growth or height is influenced by genetic factors, environmental factors, and medical conditions. The National Center for Health Statistics (NCHS) has developed age- and gender-specific growth charts for health professionals to track children's height over time. Height is converted to height-for-age, often expressed as a percentile. Children growing between the fifth and ninety-fifth percentiles are considered to be growing within normal limits.

Children whose height is below the fifth percentile may be classified as stunted or of short stature. Stunting, defined as height-for-age that is more than two standard deviations below the NCHS or World Health Organization (WHO) International Growth Reference, serves as a general indicator of a child's nutritional status over long periods of time. Growth stunting is a gradual process that occurs in response to chronic biological insults, including malnutrition and infectious diseases, during periods of linear bone growth. It often begins in utero and extends through the first two years. Childhood stunting is closely associated with poverty and is often used as a population-based indicator to compare nutritional adequacy across countries. Without environmental changes, such as adoption, stunting can lead to a permanent reduction in growth. Thus, children who experience stunting early in life are often shorter during childhood and adulthood than peers who had adequate early growth.

The term short stature (SS) usually refers to children whose height is compromised by medical problems, such as Turner's syndrome, growth hormone deficiency, renal insufficiency, or Prader-Willi syndrome. The term idio-pathic short stature (ISS) is used when there is no apparent explanation for a child's short stature. ISS can include children with short familial stature or a constitutional/maturational delay in development.

STUNTING

In the absence of adequate nutrients, a child's body conserves energy by limiting weight gain and then by limiting linear growth. Cross-sectional and longitudinal studies from multiple countries have found associations between stunting and children's health and development, caused by underlying factors such as malnutrition and infections. The consequences associated with early stunting include metabolic changes, depressed immune function, morbidity, mortality, delayed motor skills, delayed and irregular school attendance, low cognitive scores, and poor academic achievement. Adults with a history of stunting are at risk for obesity, reduced glucose tolerance, coronary heart disease, hypertension, and osteoporosis, as well as decreased work performance and productivity, thereby limiting economic capacity. In settings in which stunting is prevalent, the economic capacity of the entire society may be diminished.

The United Nations Standing Committee on Nutrition estimated that in 2004 approximately 148 million preschool children (27 percent under five years of age) in developing countries were stunted. Malnutrition is a serious global concern, and in some countries rates of stunting among children exceed 50 percent. In 2000, 70 percent of stunted children were from Asia, primarily.
South Central Asia, and 24 percent were from sub-Saharan Africa.

The primary causes of stunting are nutrient deficiencies and infection. Recent evidence has shown that cow’s milk intake is linked to linear growth, primarily by stimulating insulin-like growth factor (IGF-1). Although several nutrients have been linked to stunting, including protein, iron, zinc, copper, calcium, and vitamins D, A, and C, supplementation trials have not yielded clear findings, with the exception of 2002 meta-analysis by Brown et al. showing small but significant effects of zinc supplementation on linear growth. Intestinal infections can lead to stunting by reducing the absorption of nutrients. In environments with poor hygienic conditions, frequent infections can directly impact metabolism, particularly during infancy when nutritional demands are high and complimentary foods are introduced.

Caregiving practices can influence stunting through feeding patterns, food choices, and household stress. In food-insecure households, families may rely on foods low in macro- and micronutrients. When food is readily available, stunting rates are low. Stunted related to nutrient deficiencies can be minimized by exclusive breastfeeding for the first six months of life, as recommended by the WHO. However, in much of the world, complimentary foods are introduced before six months, often with liquids and cereals that are low in nutrients. If animal-source foods are not available, it can be difficult to provide sufficient nutrients for adequate growth. Finally, there is some evidence that severe family stress can result in diminished linear growth.

Stunting can continue into later childhood, adolescence, and adulthood, generally as an extension of prior stunting. Latin America has high rates of stunting in middle and late childhood, particularly in economically depressed areas. Although malnourished girls may have extended growth periods due to delayed menarche, they generally remain shorter than peers due to past stunting. Growth during adolescence does not typically compensate for earlier stunting.

_Catch-up growth_ is defined as growth that is greater in velocity than expected. Although catch-up growth typically occurs during periods of rapid growth in infancy and toddlerhood, it can occur in middle childhood, particularly if there are nutritional or environmental improvements. There is recent controversy about the promotion of catch-up growth, as rapid weight gain has been linked with metabolic syndrome later in life.

Historically, stunting has been addressed through nutrition supplement programs, with inconsistent success in reducing stunting and increasing linear growth. Supplementation, combined with psychosocial stimulation, can also lead to improvements in cognitive performance into early adulthood.

In Peru, where food availability is adequate and stunting is primarily caused by dietary patterns, a randomized controlled trial of a nutrition education intervention from birth found that feeding practices and dietary intake improved, and the stunting rate was reduced by two-thirds among children eighteen months of age.

Economic progress has also been linked with decreased stunting rates. For example, Southeast Asia has seen a significant decrease since 1990 corresponding with economic improvements. National factors such as energy availability, female literacy, safe water rate, amount of economy derived from agriculture, and gross national product largely explain stunting prevalence within nations.

**SHORT STATURE**

The health and developmental consequences of SS/ISS are generally less severe than stunting, depending on the underlying causes. Although early studies raised concerns about the emotional well-being of SS/ISS children, recent studies with adequate comparison groups have not found difficulties in emotional well-being or self-image related to SS/ISS.

**INTERVENTION AND TREATMENT**

Children with growth hormone deficiency have been treated effectively with recombinant growth hormone. Growth hormone therapy (GHT) has been approved for treatment of children with ISS, but it is expensive and requires injections six or seven times a week until adult height is achieved. A 2003 Cochrane review by Jackie Bryant, C. Cave, and R. Milne found nine randomized controlled trials of GHT among children with ISS, most with only short-term effects. Although GHT can contribute to short-term increases in height (ranging from 0 to 0.7 standard deviations per year), children with ISS will be shorter than peers in adulthood. There is debate on the merits of GHT among children with ISS, particularly because treatment with GHT does not appear to alter children’s quality of life. More research is needed to examine the long-term consequences of GHT, including adult stature, quality of life, and costs.

There have been concerns regarding the relation between long-acting stimulations given to children with attention-deficit/hyperactivity disorder and children’s growth. Although most studies have found no long-term negative effects on children’s height, the findings are not consistent and there are some data suggesting diminished gains in height after four years of treatment.
OTHER CONDITIONS
Severe dieting and anorexia nervosa result in inadequate weight gain (including weight loss) and may alter the sex hormones and menarche. However, there is not a clear relation between anorexia nervosa and stunting/SS. Growth history, timing of onset (before or after puberty), and duration of anorexia nervosa can impact nutritional status and growth outcomes, but have not been studied systematically.

In summary, stunting occurs early in life and can have lifelong consequences on cognition, academic performance, work capacity, and economic potential. Ensuring adequate nutrition and care through the promotion of breastfeeding; access to nutrient-rich food, including cow’s milk; and developmentally and culturally appropriate feeding practices may be effective strategies to prevent stunting.

STYLIZED FACT
The original idea of a stylized fact was introduced by Nicholas Kaldor (1908–1986) and applied to macroeconomic growth theory. Beyond the original application, the idea of a stylized fact is used throughout economics and the social sciences (and also in other scientific disciplines) as a simplifying abstraction of some social or economic process or fact. Being only a stylized fact, it is not a fact proper, but an assertion of what a researcher believes to be more or less true for a whole class of objects in question and with no reference to any concrete empirical finding. As Kaldor stated the problem of empirical observations, these “are always subject to numerous snags and qualifications” (Kaldor 1961, p. 178). Thus empirical observations and statistics distilled from them have always to be interpreted in the light of some theory. “[T]he theorist should be free to start off with a stylized view of the facts” (Kaldor 1961, p. 178)—this stylized view being a mental or verbal and in most cases still informal model of the domain of research. Empirical details, even contradictory ones, can be neglected in this early stage of research. Thus a first hypothesis explaining the stylized (and not the detailed empirical) facts can be generated.

Two stylized facts as quoted from Kaldor’s paper illustrate what Kaldor may have meant with this term:

As regards the process of economic change and development in capitalist societies, I suggest the following “stylized facts” as starting point for the construction of theoretical models: (1) The continued growth in the aggregate volume of production and in the productivity of labour at a steady trend rate; no recorded tendency for a falling rate of growth of productivity. (2) A continued increase in the amount of capital per worker, whatever statistical measure of “capital” is chosen in this connection. (Kaldor 1961/1968, p. 178)

Both of these stylized facts neglect details in the time series for measurements of productivity and capital per worker and are not even interested in the details of measurements (“whatever statistical measure … is chosen”). Moreover, a “steady trend rate” is observed—obviously a continuous deterministic function of time, as the “steady trend rate” can hardly be otherwise formalized.
Obviously, Kaldor’s stylized facts are statements about the outcome of some abstract social or economic process, not about the outcome of any concrete or real process. Thus stylized facts are not statements that aggregate the knowledge gained from the statistical analysis of many concrete social processes, but the interpretation of what a researcher distills from his or her experience of some social or economic processes. The problem with this view is that it is in a way immune to falsification, as any real economic process that is not in line with the stylized fact can be declared as something like noise (cf. Boland 1994, p. 536). Robert Solow even commented on Kaldor’s paper, saying, “there is no doubt that they are stylized, though it is possible to question whether they are facts” (Solow 1970, p. 2).

Thus, stylized facts can only be seen as starting points for further empirical and theoretical research. Recently, stylized facts have also been discussed as starting points for formal modelling and computer simulation of abstract social processes (compare, e.g., Gilbert 2000; Schwerin and Werker 2003). As Bernd-O. Heine et al. observe, the “value added by simulation models can be assessed by comparing the explanatory power of these models with respect to the relevant stylised facts to those using established methods” (2005, p. 2.11). In this sense the term is also used by Joshua Epstein (2006, p. 16), who lists several “stylized facts” such as the right-skewed wealth distributions (Epstein and Axtell 1996, pp. 7, 33–34) that were generated by the Sugarscape simulation model using a number of specified rules describing the behavior of individual agents. This is in any case an extension of Kaldor’s idea of stylized facts, as the simulation models mentioned provide microfoundation for stylized facts on the macro level.

SUBALTERN

The term subaltern derives from Latin sub- (below, under) plus alter (other) or alternus (alternate), which produced subalternus (subordinate). It designated a lower-ranking, even an inferior, individual. In the eighteenth and nineteenth centuries, subaltern was employed as a military term. In the twentieth and twenty-first centuries, under the influence of Marxism, nationalism, postcolonialist theory, and feminism, subaltern has come to be used broadly to represent subordination in social, political, religious, and economic hierarchies. Diverse aspects of societies, histories, and other human situations have been examined at the national, communal, and individual levels to recover the roles of marginalized or subaltern participants displaced by stratification. In particular the term has come to symbolize disruption and distortion of indigenous history, values, and polity in the wake of external conquest, colonization, and prominence given to Westernization at the expense of indigenous mores.

MILITARY USAGE

In martial contexts, the term was applied to commissioned military officers below the rank of captain. Essentially it denoted a junior officer, particularly at the various grades of lieutenant. Temporary command would be handed over to a subaltern officer during “trooping the colors” in honor of a monarch’s birthday.

The term was employed regularly by the British army until the Cardwell reforms in 1871. The senior subaltern rank was captain lieutenant. The junior subaltern rank in the cavalry was cornet, while its counterpart in the infantry was ensign. During the American Revolutionary War (1775–1783), the colonial army had ranks such as cornet, subaltern, and ensign—marked by green cockades.
in their hats. The rank of second lieutenant eventually replaced that of subaltern.

**SOCIOPOLITICAL USAGE**

Antonio Gramsci (1891–1937), an Italian political theorist, prominent socialist, founding member of the Communist Party in Italy (the Partito Comunista d’Italia), parliamentarian, and prisoner under the fascist regime of Benito Mussolini (1883–1945), provided the intellectual impetus for transforming the notion of subaltern into a political and social concept through his writings. He wrote of workers in Europe as belonging to classes that had been subordinated through sociopolitical hegemony, were exploited through economic methods, and were excluded from meaningful participation in the offices and benefits of the nation-state. A binary, almost dualist, relationship was said to arise between dominant and suppressed groups. Gramsci noted that such subaltern or proletarian classes could be exploited because they lacked unity and common cause and would remain oppressed unless they developed a unifying ideology that would lead them to alter the balance of power and form a new state or governing institutions that embodied and represented their wills and wishes. Gramsci, elaborating on Karl Marx (1818–1883), postulated that the working classes could and would under conditions of political coercion, economic exploitation, and social marginalization eventually develop a collective consciousness or common philosophy. That collective ideology would serve to transform them by generating self-awareness of their subordinate situations and galvanize them into resistance—thereby relocating the agency of change from the elite classes to the proletariat.

Another important intellectual influence was the notion that all forms of discourse are shaped—both overtly and inadvertently—by ideology. The literary theorist Edward Said (1935–2003) argued that the dominant views of politics, literature, religion, and history plus writings on those topics reflect Occidental, imperialist permutations. The loci of those ideological foundations were supposed to have been England and France during the colonial period of the fifteenth through twentieth centuries and the United States from the mid-twentieth century onward. The consequences of ideologies have permeated individual and collective assumptions and actions, it was suggested.

Drawing upon Gramsci’s theories and influenced by Said’s writings, an academic subdiscipline called *subaltern studies* developed in the late 1970s and early 1980s. Other influences on the development of the concept of subaltern into a theoretical framework that has displaced previous radical frameworks, such as the notion of history as an accurate record of the past, include postcolonial historiography (on which it became a major influence as well) and deconstructionism. Subaltern studies attempt to offer a theory of change grounded in notions of dominance; colonialism; subservience; alienation, including loss of self-identity; resistance; confrontation; and transformation. It postulates that even when marginalized, those who are oppressed can display agency. The common people are regarded as closely if not completely synonymous with the subaltern classes within each society. The elite of each society, whether of indigenous or expatriate origins, are designated as the dominant groups. Exploitation of the subaltern by the elite is considered an existing precondition that must be acknowledged and investigated in order to comprehend the masses in each society. The field of subaltern studies can therefore be viewed as a form of postcolonial studies.

Ranajit Guha, a historian studying South Asia, has been highly influential in popularizing the term *subaltern*, in defining its mandate and intellectual parameters, and in applying resultant concepts to historical and contemporary sociopolitical issues. He also edited several volumes of *Subaltern Studies* and anthologies drawn from those volumes. Guha and other scholars working on subalterns, such as Gayatri Chakravorty Spivak, Dipesh Chakrabarty, and Homi Bhabha, have suggested that attempts to reconstruct past events—that is, the process of historiography that produces historical accounts—is inextricably bound with and constantly reflects the impact of interactions between dominant or elite and subordinate or subaltern groups. Guha critiqued elitism by colonialists and nationalists while urging that historiography be constructed from below, not above. Spivak raised the issue of agency among the subordinate. Chakrabarty has examined reasons for historical accounts remaining centered on the state. Partha Chatterjee and Gyanendra Pandey have focused on the fragmentary aspects of history, memory, and historiographical accounts. Shahid Amin analyzed relationships between peasants and capitalists in economic production. Amin also demonstrated how and why accounts of the past are reshaped by individual and collective memory to fit new predilections. Focusing largely on the historiographies of colonialism in India and of subsequent Indian nationalism, they have proposed that those accounts were shaped by elitist British feudatory imperialism and by neo-elitist Indian bourgeois patriotism, respectively. As such, they conclude that established historiography and histories should be rejected as unrepresentative and inaccurate. The spotlight of inquiries into societies should be on the contributions of the people rather than on the accomplishments of the elites, according to scholars utilizing methodologies that incorporate the concept of the subaltern.
INTELLECTUAL IMPACTS OF SUBALTERN STUDIES AND SUBALTERN AS A CONCEPT

The term subaltern has come to be used to denote the underclasses of societies and often replaces other designations for those lower classes. Those groups are thereby distinguished from members of the ancien régime and from members of the new elites. The term has been employed in the contexts of investigations into political, religious, and social interactions between dominant and subordinate groups. Such studies have examined not only agencies of change but also how and why particular ethnoreligious communities, societal classes, and economic clusters are displaced by the might, convictions, organization, and vitality of other, emergent new elites. Moving beyond a rejection of established methodologies for analyzing societies, the study of subalterns has expanded to include investigations of social transformation and inquiries into how and why some groups developed into elite classes who control resources and perpetuate stereotypes, while other groups become subaltern communities experiencing crisis and displacement. Studies of the subaltern have suggested that the actions of elites and subalterns are affected by regional religiopolitical and socioeconomic factors and that therefore neither group can develop homogeneously. Indeed conflation and separation of modes of domination and subordination seem to have differentially determined the relationships that arose between elites and subalterns living in diverse areas.

It has been recognized that the presence of elitist and subaltern classes affects not only the patterns of interaction between groups but also influences the historiography of each community. The official historical record, often crafted by elites and instilled with a sense of social dominion and political hegemony, must be read not simply as a record of the past but also as an elite ideological product of rule that may have slowly but surely appropriated aspects of the subordinated people’s past. This increasing marginalization of subordinate communities and individuals could even eventually reduce references to members of the indigenous confessional group to fleeting stereotypical images.

Examples from historical contexts to which the term has been applied by modern scholars include the dhimmi or protected minority communities of Jews, Christians, and Zoroastrians in the medieval Middle Eastern Islamic caliphates of the Umayyads (661–750) and the Abbasids (750–1258), the peasants and workers of early modern France (1492–1789) and tsarist Russia (1721–1917), and the indigenous working classes of British India (1858–1947).

Reassessment of the concept of the subaltern and of the field of subaltern studies has commenced with deliberations regarding their significant contributions and limitations. Indeed the representativeness of subaltern studies can be questioned in terms of selectivity of topics, choice of source materials, and parameters of inquiry. Sumit Sarkar in particular has noted a reductionist tendency that excludes the complexities inherent in historical events while simultaneously being “simplistic and retrogressive” in paying short-shrift to the impacts of precolonial hierarchies (1997, p. 51). An original founder of subaltern studies turned critic, Sarkar perceives subaltern studies as mired among forms of Marxism recast in the guises of cultural, class-based, and minuita or fragment-focused investigations. Achin Vanaik, who approaches disenchantment for subaltern studies from the viewpoint of a political scientist, conlates it with postmodernism and post-structuralism. He notes a tendency to ground many studies on the subaltern in an assumed notion of secularism. Vinay Lal has raised the issue of why studies of the subaltern constantly utilize Western theories to comprehend Eastern data rather than turning to Oriental models to comprehend those who were and are subordinated. Lal also pushed for a more nuanced appreciation of the nexus between history and myth and of influences by the latter on the former’s creation, propagation, and preservation. Dane Kennedy and Richard Eaton have critiqued the rigid framework of the subaltern specifically and the amorphousness of cultural studies generally. Moreover the disillusionment and radical dissent with historiography that spawned and shaped inquiry into the situations of subalterns have become relatively mainstream in academia and broader intellectual settings.

Overall it could be suggested that historiography and other analyses of past and present societies benefited from being reshaped through inclusion of the subaltern or subordinate within the basic repertory of historical themes, events, and agents.

SUBGAME PERFECTION

In a Nash equilibrium strategy profile, every player plays the best response against the other players’ strategies specified in the profile. For extensive form games where players move sequentially, one may use this notion, treating players’ strategies as complete plans of action before the play begins. However, this concept ignores the sequential structure, and hence, sometimes may not be justifiable.

Consider the entry-deterrence game in Figure 1, in which there are two firms (players): a possible entrant (player 1) to an industry in which there is an incumbent (player 2). The potential entrant moves first and has two choices—to enter (E) or to stay out (O). If player 1 does not enter, the game ends. If player 1 enters, the incumbent then has two options—to accommodate (A) or to fight (F).

The game in Figure 1 has two Nash equilibria: (O, F) and (E, A). Indeed, in the equilibrium profile (O, F), the entrant is playing the best response O, because the entrant believes that the incumbent will choose F. However, this belief is based on an incredible threat: F is not optimal in the unreached subgame (intuitively, the “game” below a nonterminal node) in which the incumbent has to make a choice (the incumbent does not make a choice when the entrant chooses O because the game ends).

A subgame perfect equilibrium (SPE), as defined by Reinhard Selten (1965), is a strategy profile that induces a Nash equilibrium in every subgame of the original game, even if it is off the equilibrium path. Clearly, SPE refines the set of Nash equilibria. In the above example, (E, A) is a SPE, while (O, F) is not.

Any finite extensive form game with perfect information is solved using backward induction. Backward induction finds the optimal actions of the players in the “last” subgame first, and then, given these actions, works backward to the beginning to find the SPE of the game.
Consider the two-player “centipede” game in Figure 2, in which each player sequentially chooses either to continue (C) or to stop (S). Backward induction implies that the unique SPE is S for both players in every stage.

The backward induction solution is not observed in experiments where the players continue the game for a few stages (McKelvey and Palfrey 1992). This finding questions whether rational players follow backward induction. Robert Aumann (1995), however, proved that “common knowledge of rationality” implies backward induction.

Another criticism of SPE comes from the experiments on the ultimatum game, as in Figure 3, in which player 1 offers a fraction ($x$) of a pot of money to player 2, who has a choice to accept (A) or to reject (R). The SPE outcome is for player 1 to offer the smallest money unit (say, 1c) and for player 2 to accept it. However, in experiments, offers are about 40 percent, and low offers are rejected (Guth et al. 1982). This is a violation of SPE only if we assume that the players care only about money. One may, however, test the outcomes using revealed preferences in games (Ray and Zhou 2001).

For games with imperfect information, subgame perfection is not enough to justify a solution. One should consider sequential equilibrium (Kreps and Wilson 1982).

**SUBJECT/SELF**

Many social scientists argue that the modern Western conception of the self is a social construction. In “The Subject: The Person” (1979) anthropologist Marcel Mauss wrote that the history of the modern Western self began
with the ancient Roman concept of the persona. Originally *persona* simply meant a “mask,” as in the mask that a dramatic actor would wear during ritual performances. But as time went on the notion of persona became inscribed into Roman law as an individual with rights, duties, and obligations. Every male Roman citizen was considered a “person” with ancestors, a name, a clan or family, and a right to the protections of Roman law. At the same time, a slave had no personality, no ancestors, no right to property, no “self.” Emerging during the final days of the Roman Empire, the early Christian Church democratized this notion of selfhood by investing every human being with a “soul.” While in the human world, fundamental differences in social status remained, in the eyes of God all were equal. But this early Christian self was still distant from the modern Western notion of the person as a psychological being.

According to sociologist Max Weber, the next stage in this conceptual evolution came with the Protestant Reformation of the sixteenth century. Within the Catholic Church, persons invested with souls depended upon the mediating power of the priest for salvation. The priest took confession, provided communion, and offered contrite sinners salvation through his power to dispense God’s forgiveness. When Martin Luther and John Calvin turned against the Catholic Church, they eliminated the priest’s mediating power. The sinner’s salvation depended upon individual conscience, not the priest’s magic. With this emphasis on conscience and personal responsibility, a new notion of self emerged, a psychological being with a complex interior life visible to God but concealed from the world at large.

The Protestant notion of a rational self invested with personal responsibility became one foundation for the ideas of individuality promulgated by Enlightenment philosophers and the early classical political economists. Beginning with John Locke, the quasi-divine quality of the self became indissolubly linked with private property and a new conception of political rights. For Locke, and later for Adam Smith, a natural object became personal property when the individual mixed his or her labor with the thing. This early “labor theory of value” made it clear that the self was sacred and its holiness could be transferred to things, transforming them into individual possessions. Further, this new sacred self had the capacity to challenge the so-called divine right of the absolutist sovereigns that had ruled Europe for almost a thousand years. Now every individual had the same God-given right to self-government and individual rationality. During the eighteenth and nineteenth centuries, a wave of republican revolutions washed over Europe and the Americas. Under these new republican regimes, the state was considered a servant of the people; the people were thought to be a collection of self-governing, self-possessed individuals.

But beginning in the late nineteenth century, notions of the centered, rational subject were increasingly called into question by philosophers and social scientists. For instance, Friedrich Nietzsche conceived of the individual as an instinctual cauldron propelled by the “will to power.” This will to power drove the first human beings to excesses of bloodlust and cruelty as they expressed their individual sovereignty through the domination of others. But this changed as the original sovereigns entered human society. Social discipline no longer allowed the free expression of the will to power, and the instinct for domination turned inward. That repression of instinct led to the rational, centered, subject conscious of her or his guilt—the bad conscience of antisocial desire. Building on Nietzsche’s notion of the disciplinary self, twentieth-century scholar Michel Foucault produced a series of historical studies documenting techniques that created the modern subject. In *Madness and Civilization* (1965), Foucault argued that while madness had often been punished in early modern Europe, it was not until the late eighteenth and early nineteenth centuries that the modern asylum took shape. This institution operated differently than earlier forms of incarceration. A disciplinary arrangement, in which the “insane” subject was made to feel guilt for “transgression” against reason, created a new kind of person, a self whose interior life was governed by a persistent internalized self-surveillance. As a site for the inscription of social power, the subject internalized the asylum.

More recently, many feminists and postmodernists argued that the “will to power” itself was the product of this rational, alienated individuality. In her essay “The Feminist Standpoint” (2004), Nancy Hartsock wrote that as “a consequence of this experience of discontinuity and aloneness, penetration of ego-boundaries, or fusion with another is experienced as violent” (p. 46). The self seeks to escape its internalized prison through contact with others, but the only escape seems to be through violence, violation, and domination. Sexuality itself becomes tangled in this process, and the masculine self often sees the object of its desire as a thing to be conquered. But another path is possible. Mutuality, rather than domination, could satisfy the desire for fusion. Such mutuality, however, depends on a new kind of subjectivity, a self decentered, continuous, and open to transformation.

SUBJECTIVITY:
OVERVIEW
In emulating the success of the physical sciences, the social sciences have traditionally been committed to the paradigm of objective knowledge. The norm of objectivity was understood as an ideal of disinterested, factual, replicable, lawlike knowledge of social reality, a type of knowledge that would demonstrably transcend both ideological controversies and commonsense knowledge, indeed a knowledge wholly independent of human interests, passions, and all subjective entanglements. Not surprisingly, this image of science polarized epistemological disputes into two extreme camps, the objectivist persuasion defending the ideal and a range of dissenting voices questioning the possibility or desirability of a purely objective knowledge of social life. Perspectives from the latter camp shared the belief that an authentic social science must accept the radically subjective nature of its research fields and devise methods and approaches to capture the phenomena of subjective life. What follows is a brief survey of some of these approaches to subjectivity.

Given the importance of human emotions, intentions, and reasoning in modern thought, it is useful to begin with philosophy. The founding moment of modern philosophy lies in René Descartes's (1596–1650) defense of the cogito, the irreducible moment of subjective consciousness that persists as a foundation of objective, mathematical knowledge. Following Descartes's lead, we see the “philosophy of subjectivity” branching into its various forms: the explorations of Immanuel Kant (1724–1804) and Johann Fichte (1762–1814) of the transcendental subject; G. W. F. Hegel's (1770–1831) historicized vision of subjectivity as a genetic formation of “spirit” (in the 1807 Phenomenology of Spirit); Karl Marx's (1818–1883) materialist account of the subject of history exemplified by revolutionary agency and praxis; and the emergence in the first part of the twentieth century of phenomenology as a descriptive philosophy of lived experience (in the work of Edmund Husserl [1859–1938] and his students).

There were also parallel movements within the human sciences. The debate between objectivism and subjectivism first came to public attention in the dispute at the end of the nineteenth century within German sociology between the Naturwissenschaft and Geisteswissenschaft images of science. Where the “natural science” model aspired to uncover objective laws, the “human sciences” foregrounded the “spirited” realms of human action, conscious agency, and the intentional life of singular individuals embedded in particular historical contexts. The well-known defense of subjective cognition in the work of Wilhelm Windelband (1848–1915), Heinrich Rickert (1863–1936), and Wilhelm Dilthey (1833–1911) entered modern sociology in Max Weber's (1864–1920) version of a “sociology of action” based upon understanding actors’ motives (the so-called Verstehen or “understanding” approach to historical and social explanation). The subjective experience of historical agents is not to be reduced or discounted; rather, it is to be recovered through situationally sensitive contextual methodologies. Alongside the legitimate claims of quantitative methodologies, the social sciences must construct new and imaginative “qualitative” approaches to intersubjective experience.

Weber's methodological writings were given a phenomenological grounding in the work of Husserl's student, Alfred Schutz (1899–1959). Essentially Schutz followed Husserl's argument that all scientific knowledge has its foundations in the pretheoretical world of practical action, the Lebenswelt or lifeworld of everyday experience (Husserl [1954] 1970). Rather than treating subjectivity as an irrelevance or hindrance to objectivity, the social sciences could only achieve rigorous knowledge by making this “subjective world” of practical life its central topic. The human sciences, in other words, presuppose a phenomenology of the social world (Schutz 1967).

Other traditions had come to the same conclusion from different routes. One of the most notable of these is the tradition of American pragmatism and its sociological...
correlate, symbolic interactionism. Theorists such as William James (1842–1910), John Dewey (1859–1952), and George Herbert Mead (1863–1931) viewed the social world as the outcome of the reflexive interaction of conscious agents. Human beings act and relate to one another through communicative, symbolic means. Because individuals symbolically construct their lifeworlds, the interactional processes involved must form the first topic of a genuine social science. When combined, European phenomenological sociology and American interactionist sociology have given rise to a wide range of approaches to subjective experience. Among the most influential of these are phenomenological sociology interpreted as a radical sociology of knowledge (exemplified by the work of Peter Berger and Thomas Luckmann [1966]); the ethnomethodological sociology of Harold Garfinkel (1967) and Aaron Cicourel; the language-based perspectives of conversation analysis; the interactionist sociology of Erving Goffman (1922–1982) (1974) and the microsociology of subcultures and personal worlds influenced by Goffman’s work (e.g., Becker 1964; Glaser and Strauss 1967; Sudnow 1972); phenomenological psychology and humanistic psychology (Pilch and Sills 1973); social studies of science as a “subjective construction”; and so on. In addition, we might mention the interdisciplinary-wide movements of qualitative methodology, feminist epistemology, structuration theory, and recent forms of critical theory (influenced by the work of Jürgen Habermas).

In the tradition of “continental philosophy,” the subject and subjectivity occupy a fundamental role in a number of theoretical perspectives—most notably in the development of semiotic and structuralist ways of thinking that rejected the Cartesian cogito and “humanist” subject, and more recently in various strands of poststructuralist thought in which we find something like “the return of subjectivity.”

In the tradition of metaphysical humanism, the transcendent subject is thought to constitute the “object” through its active processes of representation (Kant, Arthur Schopenhauer [1788–1860]) or intentional syntheses (Husserl, Max Scheler [1874–1928], Jean-Paul Sartre [1905–1980], Maurice Merleau-Ponty [1908–1961], Paul Ricoeur [1913–2005], and others). The “world” is the totality of phenomenal appearances given to the constituting subject. Objects are “correlated” to subjective activities, functions, representations, and practices. This has been called the “philosophy of consciousness.” Questioning the primacy of consciousness produces a range of antisubjective positions. In this context, we might view psychoanalysis as the key to the rejection of the primacy of pure consciousness, with Sigmund Freud’s (1856–1939) attempt to dethrone the privileged position of subjectivity by exploring the anonymous functions of desire and unconscious experience. Psychoanalytically oriented thought contests the primacy of the ego, particularly in the guise of the subject understood as a stable, proprietorial center of conscious acts. The structuralism of Roland Barthes (1915–1980) and Louis Althusser (1918–1990), for example, has extended this criticism by seeing the self as a “subject-position” created by ideological practices and social discourses.

This critique of the subject opened the way for a much more complex and diverse problematic of subjectivity—emphasizing the changing historical, institutional, and cultural forms adopted by the subject within different fields of power (here the work of Martin Heidegger [1889–1976] and Michel Foucault [1926–1984] can be mentioned). More recent theorizing has criticized the Cartesian subject as an ideological pillar of masculine, Eurocentric culture. As black feminist and postcolonial theory has argued, the “white mythology” of the occidental subject helps to sustain patriarchy, women’s oppression, colonialism, and phallocentric institutions more generally. Rather than positing a disembodied, essentialist, and metaphysical “subject,” the task poststructuralist and postmodern thought has set for itself is to deconstruct all essentialist conceptions of the subject in order to investigate the concrete relations and discourses that create different historical forms of embodied subjectivity.

SUBJECTIVITY: ANALYSIS

The terms *subject* and *subjectivity* are employed in the humanities and social sciences in contradistinction to the notion of the self or selfhood. The latter terms traditionally suggest the idea of identity as a personal possession and of individuality as both unique and autonomous. The notion of the subject is more ambivalent in that the term at once denotes a person under the control or influence of other people or external forces—that is, a being literally or figuratively subjected to such forces and influences—and an individual agency that thinks, feels, perceives, intends, and acts in its interaction with other people and the outside world. In contrast to the self, regarded as a stable human essence and the controlling center of its own actions, the subject in contemporary critical theory is conceived as at once active and passive, and as the product of its inscription in language, politics, and culture. This so-called de-centered subject is the result of a thorough rethinking of the notion of subjectivity during the second half of the twentieth century. As such, it forms a radical break with some of the earlier theories of the subject in which it nonetheless finds its foundations.

The term *subject* in relation to human consciousness finds its origins in German idealism. Idealists, such as Georg Wilhelm Friedrich Hegel (1770–1831) and Immanuel Kant (1724–1804), assume, albeit with considerable differences in their accentuations, that only mental entities are real. Physical things, therefore, exist only in the sense that they are perceived by the controlling center of the mind. Similarly, René Descartes (1596–1650), firmly rooted in the historical intellectual movement the Enlightenment or the Age of Reason, posits that the only immediately and directly perceptible forms and objects of knowledge are those that are part of one’s state of mind. External realities merely exist as ideas or pictures in the mind. The only incontestable truth-claim pertains to one’s consciousness, hence Descartes’s famous dictum: *Cogito, ergo sum*—“I think, therefore I am.” Descartes’s model forms the basis of all subsequent theories of the subject as an autonomous being that, in being aware of its capacity for thought, is conscious of its existence. Although there are considerable differences between Descartes’s position and idealist notions of the subject, they share in common an emphasis on the human powers of perception, rationality, and free agency—on the central position of human consciousness from which all forms of knowledge and meaning are suggested to spring.

MODERNIST INFLUENCES

While philosophers such as Søren Aabye Kierkegaard (1813–1855) and Arthur Schopenhauer (1788–1860) were among the earliest contestants of idealist and rationalist notions of subjectivity, the most immediate precursors of the postmodern de-centering of the subject are three disruptive thinkers who can be jointly associated with the rise of modernism in mid–nineteenth-century western Europe: Nietzsche, Marx, and Freud.

Friedrich Nietzsche (1844–1900) took Schopenhauer’s notion of the subject as a figment of the philosophical imagination a step further by claiming that “subjectivity is the product of repressive value systems” (Cavallaro 2001, p. 88). Arguing that there is “no doer behind the deed,” Nietzsche attacks the subject in its foundations, exposing the Cartesian notion of its essential autonomy and rationality to be based on a questionable premise since the existence of thinking can never be fully proved. As a grammatical fiction, the subject has no existence as a stable substance or essence but is only the product of dominant ideologies.

The psychoanalyst Sigmund Freud (1856–1939) further undercut the presumed self-presence and unitary nature of subjectivity by introducing the notion of the unconscious and exploring its operations as among the most powerful forces in psychic life. The Freudian subject is split and divided against itself both because of the separation between conscious and unconscious psychic contents and because of the fundamentally contradictory and divisive drives that go into the subject’s making. Largely unknowable to itself and profoundly determined by its early experiences within the family situation, the psychoanalytic subject defies any form of self-determination and self-knowledge, explains Mikkel Borch-Jacobsen in *The Freudian Subject* (1988).

The political economist and socialist revolutionary Karl Marx (1818–1883) saw the Cartesian notion of the subject as an ideological ruse that merely served to sustain the liberal theory of the social contract. Instead of conceiving the subject’s consciousness of itself as the only ver-
ifiable reality, he argued that the material world is real and that people’s ideas about and perceptions of the world are the results, not the causes, of their experience of its realities.

Postmodern thinkers, however diverse in their emphases in approaching the problem of the subject, all take their cues from these three fundamental challengers of Enlightenment thought. Michel Foucault (1926–1984), for example, follows in Nietzsche’s footsteps by investigating the processes through which the subject is produced within specific historical and ideological contexts. Ladelle McWhorter explains in *Bodies and Pleasures: Foucault and the Politics of Sexual Normalization* (1999) that Foucault takes structures of knowledge and power to be equally enabling as constraining forces to produce subjectivity. Foucault therefore focuses on the ways in which even the human body cannot be said to have any meaningful and socially intelligible existence outside the discourses—sets of statements that define a cultural object, thereby calling it into being—that produce it.

Jacques Lacan (1901–1981) builds on the Freudian notion of the subject by making language central to psychic development. The Lacanian subject is alienated from its physical reality and the plenitude of its initial indivisibility from the mother in two stages. The first comes when the subject (mis)recognizes itself in the mirror and begins to identify with this image, thus building up an essentially imaginary sense of itself. The second and even more decisive moment at which the Lacanian subject is split from the Real is when it enters the realm of language and can henceforth exclusively identify and know itself in symbolic terms (Grosz 1990).

Taking Marx’s analysis of class relations as his point of departure, Louis Althusser (1918–1990) locates the emergence of the subject in ideological structures—or belief systems—which, he maintains, “seduce” individuals to take up their socioculturally determined positions within the system of social relations (Hall 2004, p. 85). Constituted through the process of interpellation—the process by which ideology addresses the individual subject and therewith effectively produces him or her as an effect—the Althusserian subject likewise flies in the face of the classical definition of the subject as cause and substance.

THE POSTMODERN SUBJECT AS SOCIAL CONSTRUCT
Whether defined as the product of power/knowledge (Foucault), language (Lacan), or ideology (Althusser), the postmodern subject is essentially a social construction, the result or effect of systems of meaning and knowledge that always precede him or her, both individually and collectively. Since such systems are both multiple and sociohistorically specific, changing over time, and cross-culturally diverse, subjectivity can neither be seen as unitary nor as a universal phenomenon transcending historical and social boundaries. What is more, the location of the emergence of the subject in systems that precede it, and whose operations necessarily exceed any individual’s control, definitively puts paid to the Cartesian notion of human consciousness as the center of control over its own being. While postmodernists thus emphasize the subject’s subjugation to the structures that produce him or her, thereby privileging the passive aspects of the term, this is not to say that individual subjectivity is denied any possibility for activity. Since ideological systems and structures of meaning and knowledge can only operate through their bearers, even the de-centered, split subject of postmodernity can be considered potentially endowed with a certain form of agency. The ambivalence of the term *subject* is ultimately maintained by the fact that subjects, though variously produced by external forces and thus by no means masters of their selves, also actively function within their constitutive outsides, whether in conformity with prevailing norms and meanings or in deviation from or actual defiance of their regulatory operations. As a produced effect of discourse, language, or ideologies, the postmodern subject is constituted in a double bind.

SUBLIMATE
The Latin word *sublimis* means lifted up, elevated, lofty, eminent, distinguished, a verbal chain containing the movement of going from lower to higher. The *Oxford English Dictionary* defines the verb *sublimate* as “to raise to
high place, dignity or honor”; “to act upon (a substance) so as to produce a refined product”; “elevation to a higher state or plane of existence; transmutation into something higher, purer, or more sublime.” In Civilization and Its Discontents, Freud uses this metaphorical structure to address how humans sublimate their instincts toward the higher plane of culture, or civilization: “Sublimation of instinct is an especially conspicuous feature of cultural development; it is what makes it possible for higher psychical activities, scientific, artistic or ideological, to play such an important part in civilized life” (Freud 1930, p. 97). In an earlier work, Freud had specified that he was addressing sexual drives: “Sublimation … consists in the instinct's directing itself towards an aim other than, and remote from, that of sexual satisfaction” (Freud 1914, p. 94). The sublimation of instincts—deflecting them away from sexuality—is aided by developmental processes of identification, inhibition, and displacement, which change libidinal instincts into “impulses of affection” (Freud 1924, p. 177). Although many individuals never reach this developmental level, sublimation still plays a role in their lives; hence the wide range of psychoanalytic formulations that attempt to take into account the multiple functions of sublimatory activity.

In Freud's formulations he presumes the individual has already achieved a separate existence from family members and has established his or her status as an individual with stable boundaries. Many other psychoanalytic texts address an earlier set of developmental issues in which stable boundaries between self and other have not yet been established. For example, John Gedo (1996) discusses the role of sublimation in individuals coping with psychotic disintegration. Edward Glover suggests that sublimation is a “process which affords the maximum protection from illness with the minimum expenditure of energy” (Glover 1931, p. 280). Heinz Kohut (1976) notes the function of sublimation in maintaining self-object relations in which an art object serves to restore a sense of self-cohesion by fulfilling a function the self cannot provide. Melanie Klein views sublimation as an attempt to repair the damage done to an internalized object as a result of hate and aggression: “The attempts to save the loved object, to repair and restore it, attempts which in the state of depression are coupled with despair, since the ego doubts its capacity to achieve this restoration, are determining factors for all sublimations” (Klein [1935] 1948, p. 290).

Once stable boundaries have been established, the individual is capable of relating to others as separate, capable of “object relationships” with all their complexity of desire, frustration, approach, avoidance, and expectation. Some formulations address the function of sublimation in sustaining the capacity for object relationships or even providing substitute objects. Michael Balint writes that “all sublimations, and especially the form of sublimation called art, are a kind of deception, are underhand ways of getting back to real personal objects” (Balint 1959, p. 115). For Volney Gay sublimation is a form of “object relatedness” protecting us “from the terrors of schizoid loneliness” (Gay 1992, pp. 292–293). The work of Gedo and Arnold Goldberg (1973) suggests four levels of sublimation: (1) Sublimation serves to prevent psychotic disintegration by providing desperate measures of marking a differentiated status. (2) Sublimation assists in sustaining psychological cohesion by providing self-objects that serve the self’s narcissistic needs. (3) Sublimation affords object relationships. (4) In Freud’s terms, sublimation enables one to bypass repression and experience gratification without guilt.

In his works D. W. Winnicott describes sublimation as beginning with the union of baby and mother and continuing throughout life “in the intense experiencing that belongs to the arts and to religion and to imaginative living, and to creative scientific work” (Winnicott [1951] 1975, p. 242). This view is “post-Freudian” in the sense that sublimation is not about bypassing repression so as to avoid guilt but rather taking stock of separateness and achieving an experience of re-joining. Hans Loewald views sublimation in these terms, observing that sublimation aims to restore, at least partially, the “original unity” of baby and mother; sublimation “is a kind of reconciliation of the subject-object dichotomy” (Loewald 1988, p. 20). For Jacques Lacan sublimation provides access to an archaic experience preceding the subject-object distinction, the point marking the loss of immediacy with the mother’s body.

Subliminal Suggestion

Subliminal suggestion occurs when messages or ideas that are perceived below (sub) the threshold or limen of conscious awareness influence thoughts, feelings, or actions. A message, object, concept, idea, or other stimulus is perceived subliminally when it is processed at a sensory level (visual or auditory) without an accompanying conscious sensory experience. When environmental stimuli (words, symbols, sounds) are subliminally perceived and encoded, mental representations of these stimuli and associated mental constructs are activated. The internal activation of mental representations makes schematically related constructs, goals, and behavioral tendencies more accessible in memory. Consequently, subliminally perceived messages may be “suggestive” of those behaviors that are mentally activated, as their heightened accessibility increases the likelihood that they will be enacted.

Auditory or visual stimuli may be processed nonconsciously under a variety of conditions. Images embedded within complex patterns and vocal messages that are masked by surrounding noise may not be consciously recognized, but implicit tests of familiarity demonstrate that these messages or signals were subliminally perceived and processed. Laboratory studies investigating the limits of subliminal influence most commonly prime behavioral tendencies by flashing words or images on a computer screen for 100 to 300 milliseconds—too quickly to be consciously perceived.

In the late 1950s, subliminal suggestion was claimed to be a commonly used method of influencing consumer purchase behavior at a nonconscious level. This notion was largely popularized by Vance Packard’s 1957 book, The Hidden Persuaders. This book detailed a study conducted by James Vicary in which theatergoers were subliminally exposed to the messages “buy popcorn” and “drink Coca-Cola” as they were flashed, for a third of a millisecond, onto the picture screen during the movie. Vicary claimed that subliminal exposure to these advertisements caused a rise in Coca-Cola and popcorn sales of 18 percent and 58 percent respectively.

Vicary later admitted that his study was fabricated and hence there was no substance to the claim that subliminal messages were an effective means of persuasion. In 1973, however, Wilson Bryan Key’s book Subliminal Seduction generated great public concern that subliminal suggestion was practiced widely among advertisers in the United States. Consequently, the Federal Communications Commission declared that the insertion of subliminal messages in advertising was a form of intentional deception that was contrary to the public interest. Hence, marketing professionals concur that the use of subliminal messages in advertising is unethical and could have potentially disastrous consequences for public relations if uncovered.

Beyond these ethical considerations, the effectiveness of advertising with subliminal suggestions is scientifically questionable. Extensive research into implicit (nonconscious) cognition and behavior in the psychological sciences demonstrates that the “suggestive” influence of subliminally perceived messages is limited to words, images, or sounds that are highly familiar, abstract, and simple.

The meaning of a perceived cue cannot be processed at a subliminal level unless there is a preexisting mental representation of this cue. Consequently, it is unlikely that novel images, words, or concepts will influence thoughts and behaviors when they are subliminally processed. Thus unfamiliar product brands will not reliably influence consumption or purchase behavior if they are not consciously perceived.

The meaning or behavioral message associated with subliminally perceived cues is general, not specific. Mental

John P. Muller
representations of the meaning of such perceptual cues are categorical; that is, the meaning of subliminally perceived cues is construed abstractly. Consequently, subliminally perceived messages may only succeed in influencing one to engage in a related activity, if at all. For instance, the subliminal perception of a Coca-Cola brand name may bring the idea of “drink” or “thirst” to consciousness and activate a desire to purchase a drink, but the drink purchased will not necessarily be Coca-Cola. Therefore, subliminal messages are at best suggestive, but never persuasive.

Implicit cognition research has consistently demonstrated that the meaning of complex messages cannot be processed at a subliminal level (Greenwald 1992). The meaning of the words eat and drink may be processed subliminally, thereby increasing the likelihood that the perceiver will engage in these behaviors. However, more complex messages that include brand names, punctuation, or sentences are not likely to have such a suggestive effect.

SUBSIDIES
A subsidy is a benefit, in some form, which one would not otherwise receive, but the concept is more complex than such a simple definition implies. The twin cruxes of the problem are the determination of the basis of comparison by which a subsidy is reckoned and whether the comparison is treated positively or normatively and if the latter negatively or affirmatively. Consider the following examples:

A rich uncle will pay your college tuition and living expenses if you go to college.
Parents arrange for one child to inherit more than the other, where the norm is equal shares.

A polluting firm may be offered a payment if it will stop its polluting activities.

A firm producing multiple outputs allocates costs on paper so that they differ from what they actually are; for example, residential customers pay telephone rates below their cost of service and business subscribers pay more than their cost of service, or, more specifically, poor residential customers benefit from below-cost rates that are financed by the higher rates paid by wealthier customers.

An industry is given payments by government so that it will expand, or not contract, thus providing more employment than it otherwise would.

A shift from one costing procedure to another increases some measured costs and decreases others.

A change from one institution to another changes the distribution of gains and losses.

Whether or not a subsidy exists in each of the examples depends on the choice of basis; in the last two examples, the subsidy depends on the cost procedure or the institution used as the basis of comparison.

Accordingly, a decrease in business telephone rates implies a subsidy to business if one believes the lower residential rates are proper; if one thinks that low residential rates involve an improper subsidy to householders, an increase in those rates (and a decrease in business rates) will end the subsidy. A change in rates based on a shift in costing procedure means gainers are being subsidized if you posit that the initial costing procedure is correct; but if you consider the initial costing procedure to be erroneous, those people are now not being subsidized and others are. A change from one costing procedure to another creates a subsidy to gainers if you assume that the initial costing procedure is proper; they are getting more than they should. If you think the second costing procedure is correct, then the gainers are not being subsidized; they are getting what they should. Non-normatively, changes in costing procedures bring about different net income changes.

The foregoing examples are stated in largely non-normative terms. The concept of subsidy often has a negative normative connotation when it could have an affirmative one—it depends on the choice of base as to what people are entitled. The “choice of base” is illustrated in the following examples.

The rich uncle may be spoiling you or he may be contributing to the family’s practice of taking care of its own, depending on what view, or base, one takes.
The parents may be punishing one child or they may be providing for a child so ill that he or she cannot support himself or herself. If one feels that children should be treated equally, the ill child is being subsidized. If one feels that distribution of an estate should be a matter of relative need, then no subsidy in a pejorative, i.e., negative, sense is created.

One may feel that polluters should not be rewarded for polluting by paying them not to pollute; indeed, they should be taxed if they pollute. Yet, the tax and payment policies are analytically equivalent. Imposing a tax on pollution lowers the polluters’ profits, thereby inducing them to spend money to install pollution-preventing equipment to avoid paying the tax; similarly, providing a subsidy to install such equipment can induce the firm to enhance its income position by receiving the subsidy. In each case, the firm is led to change its behavior, and the result is less pollution.

An alternate definition of a subsidy is a benefit, in some form, that is not received through the market. This definition posits market distribution as the base. Several problems arise with this definition. Firstly, the market is not the only decisional arrangement in society; government and nonprofit organizations are other modes of distributing gains and losses, and positing market distribution negates these other modes. Secondly, there is no such thing as “the market”; there can be different markets, all of which are the result of the actions, plans, and strategies of firms and of governments to influence the structure and performance of markets. Distribution through one market is a subsidy if an individual considers another market to be proper. Different structures of power lead to different structures of rights and of markets; whether a subsidy exists will depend on the structure posited as proper.

For the rich uncle, one may substitute one’s church or the government or other nonprofit educational and charitable institutions. These may receive voluntary donations and transfer the money to people who qualify on the basis of perceived capabilities, needs, or redistributive goals, to create and give effect to a sense of community—payments giving effect to people’s social preferences. Programs to encourage the integration of immigrants into the community may involve short-run subsidies, but they avoid the costs of unemployment dislocation and enhance productivity in the long run by improving working and other skills. The benefit so transferred may qualify as a subsidy under the definition of subsidy as a benefit which one would not receive through the market. That privileges market determination, or, more properly, the power structure that produces certain actual markets and not others, and debases other, nonmarket decisional processes.

The negative connotation of a subsidy may be warranted in the case of “pork” politics and the “Christmas tree” collection of payments and other benefits to interest groups having influence in the legislature. This view is only partly in conflict with those that see the role of government as helping to solve problems in the social interest and enabling people to receive their just due. It may be that a distinction has to be made between transfers/subsidies that represent returns to political fund contributors and those that represent putative solutions to social problems; however, the language of political symbolism is elastic enough to blur the distinction.

SUBSIDIES, FARM
Farm subsidies are monetary transfers from taxpayers and consumers to producers of agricultural commodities, and they are mostly a characteristic of high- and middle-income countries. They were first introduced in the United States on a large scale shortly after the 1929 crisis, mainly in response to fears of inadequate food supplies (Gardner 2002). Since then, subsidies have been renewed by the U.S. Congress every five to six years under legislation, the so-called Farm Bills. Farm subsidies were introduced in Europe after World War II, again as means to prevent food shortages, and were institutionalized after the introduction of the Common Agricultural Policy following the Treaty of Rome. Other countries with considerable levels of farm subsidies are Korea, Japan, Mexico, and Turkey. Farm subsidies achieved their objective of increasing food availability. However, despite huge food surpluses during the last three decades of the twentieth century, not only have they remained in place but they have been increased and applied to more commodities.

Based on their source of funding, farm subsidies are categorized as either taxpayer financed or consumer financed. Taxpayer-financed subsidies are direct transfers...
from the treasury to commodity producers; most payments are based on quantity produced or area planted, while some are based on input use or other requirements, such as conservation measures. However, because these types of subsidies cause considerable distortions to world commodity markets, countries have attempted to decouple payments from current production and instead give subsidies in the form of direct income support as a way to make them less trade distorting (Baffes and de Gorster 2005). Consumer-financed subsidies are typically associated with tariffs imposed on imports or subsidies on exports.

Farm subsidies are monitored by the Organization of Economic Cooperation and Development (OECD), which publishes detailed figures each year. During 2002–2005 total transfers to agricultural producers or consumers of agricultural products in OECD countries averaged $357 billion, of which 56 percent were financed by consumers, while the remaining 46 percent were financed by taxpayers. The European Union accounts for 39 percent of subsidies, while the United States and Japan account for 27 percent and 16 percent, respectively. The remaining 17 percent are accounted for by Korea, Turkey, Mexico, and Canada. On a commodity basis, the largest beneficiary is the milk industry, followed by producers of beef, rice, and wheat.

Because farm subsidies induce overproduction, which in turn depresses world prices, there have been attempts to limit them (Aksoy and Beghin 2004). Limiting the level of farm subsidies was first considered during the Uruguay Round (1986–1994) of multilateral trade negotiations under the aegis of the General Agreement of Tariffs and Trade (GATT). It was agreed that taxpayer-financed subsidies with the most distortionary impact on trade would be gradually reduced from their 1986–1988 level. It was also agreed that export subsidies should be eliminated, while tariffs on imports should be reduced by approximately one-third of their initial level. However, because the formulas for calculating such reductions were complicated, most countries were able to fulfill their obligations by changing the nature of subsidies rather than undertaking real reductions. The issue of subsidies was reconsidered during the Doha Development Agenda, which was launched in 2001. However, farm subsidies turned out to be one of the most contentious issues of the agenda, and the negotiations were suspended.

SUBSISTENCE AGRICULTURE
The peasant concept of the good life is the minimum expenditure of physical labor. When applied to food production, peasants expend only enough labor to grow enough food to last until the next harvest. Labor expenditures are matched to the food needed for a subsistence diet. This defines the subsistence compromise and explains why peasant societies experience endemic seasonal hunger and are vulnerable to famine conditions in consecutive poor crop years. Seasonal hunger and peacetime famine conditions affect all peasant societies regardless of race, religion, climate, population density, cultivation practices, and subsistence crops grown. Even peasant societies with low population densities that cultivate fertile soils experience endemic hunger and famine conditions.

Three social values govern subsistence agriculture: (1) equalized opportunities for qualifying households to share cultivation rights on village land, (2) minimal labor expenditures in food production (subsistence labor norms) on the assumption that every crop year will be normal, and (3) equalized sharing of harvests in poor crop years to ensure the survival of all village households. Only by analyzing the operation of the subsistence compromise at the village level can scholars and political leaders understand why seasonal hunger is endemic in peasant societies and why famine conditions recur.

LAND
The primary source of subsistence food safety for peasant households is communal land tenure, the equalized allocation of cultivation rights on land controlled by village councils. The purpose of communal tenure is to distribute enough land to qualifying households to grow subsistence amounts of food with subsistence labor norms.

Partible inheritance is the usual way for equalizing subsistence opportunities. Customary law mandates equally dividing land among surviving sons at the death of the household head. Inheriting households acquire cultivation rights to equal portions of each category of land. Each
household gets a parcel in the most fertile field (irrigated or best drained) and in as many other fields as there are variations in fertility. A common result of partible inheritance is households cultivating several parcels that are scattered on village land. As population densities increase, village land is divided into many small parcels (morselation).

Equalized access to land use is also often enforced by periodic redistribution of land by lot. Redistribution may be done annually or every second, third, fourth, or tenth year. Customary law mandates that land in communal tenure is a perpetual reservoir for periodic redistribution. It cannot be sold by occupying households because they do not own it; nor can fences be built because they would impede periodic redistribution.

When a village's land can no longer be physically divided without drastically impairing productivity, the number of parcels is stabilized. Harvest sharing, however, continues. Clifford Geertz in his 1963 book calls land and harvest sharing “agricultural involution” because it seeks to maximize the number of households that can be fed from a fixed area of arable land.

LABOR
As long as communal tenure operates, customary law protects the performance of subsistence labor norms. Control of land use allows landholding households to control labor expenditures through several strategies, the most common of which is parents’ transferring as much labor as possible to dependents. All peasant societies have high birthrates because households desire many children so that large amounts of agricultural labor can be transferred to them at a young age. Transferring agricultural labor to dependents also occurs through the use of slaves; the use of sharecroppers; the assignment of gender tasks; having multiple wives; and in India, through the Hindu caste system. These practices rely on the least motivated or physically weakest members of peasant societies to perform agricultural labor. Seasonal hunger is often an annual event in normal crop years because their inefficient labor is combined with minimal agricultural labor performed by adult male heads of households.

Peasants believe that a fixed amount of annual labor will produce adequate subsistence harvests in normal crop years although they know that not all crop years are normal. Nonetheless, they willingly risk seasonal hunger to preserve subsistence labor norms. Households always calculate how much labor is required to feed their households until the next harvest, and after this labor is performed, peasants view indolence as the proper use of time.

HARVEST SHARING
In poor crop years, customary law mandates harvest sharing, which is most clearly visible in densely populated villages that must practice intensive cultivation. Landless households acquire claims to shares of harvests, usually through sharecropping, by performing disproportionately large amounts of agricultural labor for landholding households.

The ethic of harvest sharing dampens the motivation of a small minority of households to respond to commercial incentives to grow enlarged food surpluses for sale on anonymous markets. Harvest sharing is a leveling institution that enforces a near equality in food-producing capabilities. Preventing households from growing enlarged harvests for market sale ensures that food loans (however small) are available for hungry households. The result is that households that are receptive to commercial incentives do not perform the necessary labor to grow enlarged harvests because any surpluses they produce will not be theirs to sell. Although certainly not economic, harvest sharing is the moral economy of the peasantry. It sustains subsistence agriculture because it tries to ensure that all village households will have enough food to survive poor crop years.

CULTIVATION PRACTICES
The fixed amount of agricultural labor required to produce subsistence-sized harvests is proportional to population density. Labor expenditures are minimal in shifting cultivation but increase as land is more intensively cultivated. Shifting cultivation, practiced where land is abundant and people are few, requires less per capita labor than any other cultivation practice because there is no ground preparation. Trees are cut and burned and women and children dibble the seeds of food grains (rice, barley, rye, maize, sorghum) into the ground among charred stumps and a tangle of partially burned branches. Thereafter weeding is haphazard and is done by women and children. Land is cultivated for two, three, or four years and then allowed to revert to secondary forest. In eight to twenty years the canopy of the secondary forest shades grasses to death. The forest is recut and burned and the ground replanted. Yields are low, but so too are labor inputs.

As population increases, shifting cultivation is replaced by continuous cultivation; and as population further increases, continuous cultivation evolves into intensive cultivation. The most visible signs of continuous cultivation are fields and terraces without stumps and ground preparation by plows pulled by oxen or water buffalo. Rice cultivators build terraces to retain a water cover to drown competing weeds, and seeds are broadcast sown. When rice cultivation intensifies, women plant germinated blades one at a time. Further intensification requires irrigation, double cropping, intense weeding, and fertilization. Ester Boserup (1965, 1970) has documented that a high percentage of the additional labor required for intensive cultivation is done by women.
TRADE
All contemporary peasant societies are monetized. As long as peasants control enough land to achieve subsistence diets in normal crop years, their money needs are minimal. Cultural anthropologists have documented that peasant households produce only enough exchange commodities to acquire target sums of money. Typically exchange commodities are one or two bags of grain, but they can be seeds, cotton, wool, unprocessed coffee beans, tobacco, cinnamon bark, latex sheets, or fowls.

The money acquired through trade is used to purchase a limited variety of manufactured products. Typically these products are textiles, edged tools, cooking pots, plastic pails, and plastic sandals. Manufactured products substitute for fragile handicraft products that need continuous replacement. Peasants compute the durability and utility of manufactured products over handicraft products by comparing the amount of labor required to make handicraft products with the amount of labor required to produce exchange commodities. If the terms of trade are favorable, measured in the amounts of labor saved, peasant households produce commodities specifically for sale. Often these products—coffee, tea, latex sheets—have minimal or no household use, and frequently much of the labor is done by children. Target sums of money are not incomes because in poor crop years little money is acquired and peasant households make few purchases. The welfare of peasant households does not depend on money incomes but rather on control of land use.

ECONOMIC DEVELOPMENT
Economists like Theodore W. Schultz observed subsistence agriculture without understanding the revolutionary differences between subsistence and commercial social values, between subsistence and commercial labor norms, or between communal and freehold tenure. Nor do most economists understand how assured food surpluses came to be produced in some European nations after 1600 with fewer laborers working longer hours.

Schultz's analysis of peasant agriculture is based on the false assumption that commercial social values and commercial labor norms are universal and that they operate in peasant villages. On the basis of this assumption, Schultz claimed that peasants were eager to adopt green revolution technologies, improved seed, mechanical plowing, fertilizers, all of which must be purchased if investments made them available. For Schultz and economists who followed his lead, the green revolution was technology that could magically end peasant privation. But peasant privation was not in fact ended because Schultz and most economists did not understand that peasant societies have huge amounts of unused male labor. Assured food surpluses can be produced by supervising agricultural labor—similar to labor performed on plantations. Some of this labor entails better ground preparation, timely seeding, more weeding, and better feeding of draft animals. Peasants reject green revolution technologies because increased per capita yields require adopting these technologies as a package, and applying the package requires much more labor. Only when more people must be fed from the same area of land are some green revolution technologies adopted, because they are necessary to sustain a subsistence level of food production and consumption.

W. Arthur Lewis was an experienced observer of peasant labor norms. He understood that the first step in ending subsistence privation was more agricultural labor performed by males. Unfortunately, policies prescribed by international aid agencies continue to be guided by Schultz's misconception that peasants are eager to adopt green revolution technologies. In most peasant societies per capita food production remains stationary.

BIBLIOGRAPHY
**Substitutability**

Substitutability is a fundamental concept in economics and is encountered in both consumer theory and producer theory. To illustrate, assume a finite number of commodities (say \( n \)) and consider the following (direct) utility function,

\[ u = f(x_1, x_2, \ldots, x_n), \]

where \((x_1, x_2, \ldots, x_n)\) is the commodity vector. Commodities \(i\) and \(j\) are said to be **substitutes** if

\[ \frac{\partial^2 f(x_1, x_2, \ldots, x_n)}{\partial x_i \partial x_j} < 0, \]

that is, if increased consumption of \(x_j\) reduces the marginal utility of \(x_i\), and vice versa. If the second-order partial derivative is positive, then \(x_i\) and \(x_j\) are **complements**, and if it is zero, then \(x_i\) and \(x_j\) are **independent**.

Although the sign of the above second-order partial derivative is invariant under linear transformations of the utility function, it is not invariant under monotonic increasing transformations of the utility function. The demand system, however, has the advantage of being invariant under monotonic increasing transformations of the utility function. The demand system is obtained by maximizing \( u = f(x_1, x_2, \ldots, x_n) \) subject to the budget constraint,

\[ p_1 x_1 + p_2 x_2 + \ldots + p_n x_n = y, \]

where \((p_1, p_2, \ldots, p_n)\) is the vector of prices and \(y\) is income. The demand systems is given by

\[ x_i = x_i(p_1, p_2, \ldots, p_n, y), \quad i = 1, 2, \ldots, n \]

gives the quantity demanded (of each commodity) as a function of the prices of all commodities and income.

In terms of the demand system, we can find out how the demand for good \(x_i\) changes if the price of good \(x_j\) changes. In particular, if \( \Delta x_i / \Delta p_j > 0 \), then \(x_i\) is a **gross substitute** for \(x_j\), meaning that when \(x_j\) becomes more expensive the consumer switches to consuming \(x_i\); in other words, the consumer substitutes away from the relatively more expensive good towards the relatively less expensive good. If \( \Delta x_i / \Delta p_j < 0 \), then \(x_i\) is a **gross complement** for \(x_j\), meaning that when \(x_j\) becomes more expensive the consumer reduces the consumption of \(x_i\) and also of \(x_j\); complements are goods that are consumed together (as, for example, coffee and sugar).

The definitions given above are in gross terms because they ignore the **income effect**—that is, the change in demand of good \(x_i\) due to the change in purchasing power as a result of the change in the price of good \(x_j\). The Slutsky equation—see Mas-Colell, Whinston, and Green (1995) for more details—decomposes the total effect of a price change on demand into a substitution effect and an income effect, as follows:

\[ \frac{\partial x_i}{\partial p_j} = k_{ij} - \frac{\partial x_i}{\partial y} x_j \]

where \(\frac{\partial x_i}{\partial p_j}\) is the total effect of a price change on demand, \(k_{ij}\) is the substitution effect of a compensated price change on demand, and \(-\frac{\partial x_i}{\partial y} x_j\) is the income effect, resulting from a change in price (not in income). Hicks (1956) suggested using the sign of the cross-substitution effect (that is, the change in compensated demand) to classify goods as substitutes whenever \(k_{ij} > 0\) is positive. In fact, according to Hicks (1956), \(k_{ij} > 0\) indicates substitutability, \(k_{ij} < 0\) indicates complementarity, and \(k_{ij} = 0\) indicates independence.

One important property of the Slutsky equation is that the cross-substitution effects are symmetric, that is

\[ k_{ij} = k_{ji} \]

This symmetry restriction may also be written in elasticity terms, as follows

\[ \frac{\eta_{ij}}{S_j} + E_i = \frac{\eta_{ji}}{S_i} + E_j \]

where \(\eta_{ij}\) is the elasticity of demand of good \(i\) with respect to the price of good \(j\), \(E_i\) is the income elasticity of demand of good \(i\), and \(S_i = p_i x_i / y\) is the proportion of total expenditure devoted to good \(j\).

The symmetrical terms in the above equation are the Allen elasticities of substitution, so that the equation can be written as

\[ \sigma_{ij} = \frac{\eta_{ij}}{S_j} + E_i = \frac{\eta_{ji}}{S_i} + E_j = \sigma_{ji} \]

where \(\sigma_{ij}\) denotes the Allen elasticity of substitution between goods \(i\) and \(j\)—see Allen (1938) for more details. If \(\sigma_{ij} > 0\), goods \(i\) and \(j\) are said to be Allen substitutes, in the sense that an increase in the price of good \(j\) causes an increased consumption of good \(i\). If, however, \(\sigma_{ij} < 0\), then the goods are said to be Allen complements, in the sense that an increase in the price of good \(j\) causes a decreased consumption of good \(i\).

The Allen elasticity of substitution is the traditional measure and has been employed to measure substitution behavior and structural instability in a variety of contexts. When there are more than two goods, however, the Allen
Suburban Sprawl

elasticity may be uninformative and the Morishima elasticity of substitution,

$$\sigma_{ij}^m = \frac{s_j (\sigma_{ii}^a - \sigma_{ii}^m)},$$

is the correct measure of substitution elasticity—see Morishima (1967) and Blackorby and Russell (1989). Notice that $\sigma_{ij}^m$ measures the net change in the compensated demand for good $j$ when the price of good $i$ changes. Goods will be Morishima complements (substitutes) if an increase in the price of $i$ causes $x_i / x_j$ to decrease (increase).

In the producer context, the producer’s problem can be formulated as

$$C(w_1, w_2, \ldots, w_n, y) = \min \sum w_i x_i + w_j x_j + \ldots + w_n x_n,$$

subject to

$$y = f(x_1, x_2, \ldots, x_n),$$

where $w_i$ denotes the price for input $i$, $y$ denotes output, and $x_i$ denotes input $i$. Inputs $i$ and $j$ are said to be substitutes if

$$\frac{\partial^2 C(w_1, w_2, \ldots, w_n, y)}{\partial w_i \partial w_j} > 0.$$

If the second-order partial derivative is negative, then $x_i$ and $x_j$ are complements.

As in the consumer context, the degree of substitutability between any pair of factors in the producer context is also measured using the elasticity of substitution. The Allen elasticity of substitution in the cost minimization framework can be obtained by

$$\sigma_{ij}^a = \frac{C_i \times C_j}{C_i / C_j} = \frac{\varepsilon_{ij}}{s_j},$$

where $C_i$ is the partial derivative of the cost function with respect to the price of the $i$th factor, and $C_j$ is the partial derivative of $C$ with respect to the price of the $j$th factor. $\varepsilon_{ij} = \frac{\partial \ln x_i}{\partial \ln w_j}$ is the elasticity of the demand for the $i$th factor ($x_i$) with respect to the price of the $j$th factor ($w_j$). $s_j = w_j x_j / \sum w_k x_k$ is the cost share of input $j$.

Again, as in the consumer context, when there are more than two goods, the Allen elasticity may be uninformative and the Morishima elasticity of substitution, calculated as

$$\sigma_{ij}^m = \frac{w_i \times C_{ij}}{C_j} - \frac{w_j \times C_{ij}}{C_i} = \frac{\varepsilon_{ij} - \varepsilon_{ji}},$$

is the correct measure of substitution elasticity—see Morishima (1967) and Blackorby and Russell (1989).

The conceptual foundations of the Allen and Morishima elasticities of substitution are different. The Allen elasticity of substitution classifies a pair of inputs as direct substitutes (complements) if an increase in the price of one causes an increase (decrease) in the quantity demanded of the other, whereas the Morishima elasticity of substitution classifies a pair of inputs as direct substitutes (complements) if an increase in the price of one causes the quantity of the other to increase (decrease) relative to the quantity of the input whose price has changed. For this reason, the Morishima elasticity of substitution leans more toward substitutability. To put it differently, if two inputs are direct substitutes according to the Allen elasticity of substitution, theoretically, they must be direct substitutes according to the Morishima elasticity of substitution. But if two inputs are direct complements according to the Allen elasticity of substitution, they can be either direct complements or direct substitutes according to the Morishima elasticity of substitution.

Apostolos Serletis

SUBURBAN SPRAWL

Suburbanization, the movement of resources and people out of cities, has increased sprawl: the overdevelopment, congestion, and environmental degradation of regions. Suburbanization and suburban sprawl are the result of several factors, including economic change—such as deindustrialization—that acts as a centrifugal force that propels private investment and people outward into the suburbs, large public and private investments in highways, government subsidies for low interest mortgage loans, and suburban housing development. Simultaneously, resources and people are pushed outward to the suburbs by the concentration of problems and poverty in urban...
Suburban Sprawl

The rapid expansion of the number of political jurisdictions to over 90,000 in the early 2000s is mostly due to the creation of new suburbs. Suburban political incorporation allows suburbs to insulate themselves from cities, protect their tax base and property values, build better schools, and siphon off transportation dollars and business investment. Affluent suburbs avoid most regional responsibilities and burdens. They do not pay for central city services and infrastructure that commuters use, including sanitation, police, bridges, airports, sports complexes, and so on. At the same time these affluent suburbs deplete remaining green space and endanger fragile and precious environmental resources.

As a result, the racial composition and quality of life of metropolitan areas has concomitantly shifted dramatically: suburban dwellers, who remain largely white, score higher than inner-city residents, who are predominantly people of color, in nearly every opportunity category—including income, employment, assets, quality of education, and housing—and with lower crime rates.

Conventional explanations of suburban sprawl include: (1) individual choices and cultural differences; (2) poorly designed urban renewal and social programs; and (3) deindustrialization, changing market forces, and globalization.

But others have shown that suburban sprawl is also a consequence of a host of historically created and contemporarily sustained sets of public policies and private practices. Following World War II (1939–1945), billions of dollars wielded by national, state, and local governments provided pathways out of cities for millions of white working and middle-class residents. For example, the GI Bill, the Interstate Highway Act, and home mortgage loan programs contributed to suburban sprawl. Without aid for home buying and highway construction, white middle-class exodus would not have occurred on such a large scale. In short, suburban sprawl has been subsidized. Moreover, inner-city poverty and suburban prosperity are not coincidental; they are two sides of the same coin.

Ironically, the fate of suburbs, central cities, and older suburbs are inextricably linked. Both suburbanites and inner-city residents have a stake in regional developments, partly because regional economies prosper or falter as a whole. Their destinies are intertwined. Thus, regional level solutions may be necessary to address inner-city poverty and suburban sprawl.

BIBLIOGRAPHY

The formation of middle-class suburbs in the United States beginning in the early twentieth century and expanding rapidly after World War II (1939–1945) is the result of a number of factors. A strong economy at the beginning of the century made the suburban lifestyle more accessible to many Americans. The development of lower-cost homogenized housing, such as the Sears Catalog home, made purchasing a house a realistic prospect for the middle class. In the 1920s, U.S. suburban growth surpassed urban growth for the first time (Weeks 1981). Economic factors during the Great Depression caused the growth of suburbs to decline drastically. In the late 1940s and 1950s, however, suburban growth rates resurfaced and reached their highest levels (Rothblatt and Garr 1986). This resurgence is frequently attributed to strong economic growth and social programs like the GI Bill that provided opportunities to service members after the war.

In 1947 construction began on Levittown on Long Island, New York, a project considered the start of the middle-class suburban revolution in America. The rapid expansion of the freeway system during the early 1950s made possible the development of many similar communities, as is evident in the expansion of freeways and homes in the Los Angeles area (Fishman 1987; Weeks 1981). Levittown has since become a term used to describe various social problems accompanying the formation of suburbs, including white flight, cultural wasteland, and separate spheres of family and economic life (Keller 1998).

Home ownership, achieved through the development of suburbs, is the most important factor of wealth accumulation in American society. While economic factors played a significant role in the formation of suburbs, they do not explain why middle-class Americans felt the need to escape urban areas that had previously been acceptable to them. In fact, economic factors have helped constrain suburban growth that has been driven by other factors, such as race. Prior to the twentieth century, there had been a relatively small African American population in U.S. cities. However, the migration of African Americans from rural areas in the early twentieth century brought significant white resistance and a push for racially segregated housing areas (Massey and Denton 1998). White flight, the mass migration of whites out of the cities, was hindered by economic factors during the Great Depression. Following World War II, however, the movement of whites to the peripheral areas around cities, coupled with social and institutional policies of racially restrictive housing, resulted in high degrees of racial segregation. White flight became a major factor in school desegregation policy; in the mid-1970s a debate arose over whether busing for the purpose of school desegregation would lead to increases in white flight.
School desegregation has had numerous effects on the formation and structure of America’s suburbs. In the midst of the period of white flight, the U.S. Supreme Court decision in Brown v. Board of Education (1954) led to the integration of many schools in neighborhoods that had previously been white enclaves. A number of measures were taken by white communities and conservative local and state governments to resist school integration. School busing during the 1960s and 1970s became a strongly debated issue, and residents of suburbs found they could maintain racial segregation of schools more effectively than had been possible in inner-city areas. Due to the effectiveness of suburbs as residential enclaves, white residents could gerrymander school districts in order to halt integration (James 1989). By the late 1970s, school busing had become a less pressing issue (Woodard 1998). While affirmative action policies remained in effect, opposition to such policies rose during the 1980s with the idea that the United States had transcended racial issues. As a result, there has been an increase in school segregation in suburban areas since 1989 (Reardon et al. 2000). In addition, policies still in place to aid school integration are being challenged throughout the country, despite the fact that public schools remain heavily segregated. In 2006 the Supreme Court heard arguments in two cases regarding school integration policies that some parents considered discriminatory. Cases from Seattle, Washington, and Louisville, Kentucky, reviewed whether public schools can take race into consideration in campus assignments in order to achieve racial integration. In a 5–4 decision the Court declared that schools attempting to achieve or maintain racial integration cannot do so by measures that take explicit account of the students’ race (Greenhouse 2007).

Despite the passage in 1968 of the Fair Housing Act, little progress has been made toward racial integration of suburbs (Orser 1998). The Fair Housing Act prohibited owners, real-estate agents, and renters from denying access to housing on the basis of race. The act also outlawed lying about the availability of a dwelling, and prevented blockbusting (telling white residents that minorities are moving into a neighborhood in an effort to convince them to sell) (Sidney 2003). As of 1990, only 20 percent of Americans lived in desegregated neighborhoods (Darden 1998). Housing segregation between whites and Hispanics, as well as between whites and Asians, has risen since 1980. However, studies have shown that suburbanization is tied to socioeconomic status among Hispanics and Asians, but suburbs have remained mostly closed to blacks whatever their socioeconomic status (Darden 1998). Housing discrimination has also contributed to higher levels of poverty, a lower average income, and lower life chances for those trapped in declining inner-city neighborhoods.

One result of the formation of suburbs was that people who were left behind in urban neighborhoods were forced to deal with urban decay brought about by the flight of millions out of the cities. Buildings were left empty, businesses were forced to close and move to more profitable areas. Resources previously available within cities were shifted to peripheral areas as suburbs grew. The 1949 Housing Act was designed to facilitate redevelopment in areas that had been affected by urban decay; this process came to be known as urban renewal. The act sparked a debate over how to handle such renewal. Federal subsides were given to private developers in order to generate new business within urban areas. But development was centered heavily around the interests of those in suburban areas, and little attention was paid to the needs of those living within urban areas. In addition, most urban development took place in residential areas, forcing many out of their homes. Eventually, a compromise was reached, and developers were required to find alternative housing for those displaced by urban renewal (Hays 1995). Urban-renewal plans have consistently favored the interests of the suburbs. As far back as 1766 an urban-renewal plan for London was designed around the needs of business owners with little regard for workers and lower-class citizens (Fishman 1987). Today, urban renewal still often functions in the interests of suburban residents over the poor and minorities who remain in inner cities.

From 1970 to 1990, the number of high-poverty metropolitan areas doubled; these areas are more likely to be home to traditionally disadvantaged minorities (Sidney 2003). American suburbs formed out of a desire for racial segregation. In the twenty-first century, continuing housing discrimination in America’s suburbs leads to a continuation of racial segregation with increases in economic stratification.

SUDRAS

Sudras (also Sudhra or Shudra) are people occupying a position next to the bottom of the Hindu caste system in India. Most Sudras are menial workers. At times it is difficult to distinguish Sudras from untouchables (Dalits), who stand below them and are considered to be so polluted that they are regarded as outside the caste system entirely. The Vaisya (Vaishya) or merchant caste stands directly above the Sudras in India’s cast hierarchy.

Identifying a member of the Sudra class is a matter of recognizing subtle distinctions with which one becomes familiar after living around Sudras. They are usually identified by their vocabulary, which may include vulgarities; by the towns where they live or were born; by their occupations or by their personal names, which may include a reference to their occupations; and by other subtle characteristics. By tradition when a Sudra dies, the body is taken to the burial place through a south gate because all other gates are reserved for the upper castes. There have been times when the jobs performed by Sudras were considered to be so polluting that Sudras were considered equivalent to untouchables. Strictly speaking, this would not be their status by birth but by economic actions. In addition Sudras could be exiled or slain at will.

Caste, or varna (literally, “color”), is affirmed by the Vedas as an expression of cosmic law (riti). Sudras are associated with the color black, which may have originated in the colors assigned to the various varna. One Hindu justification for the caste system rests in the belief that people were created from parts of the body of the god Purusha. Social standing is defined by the part of Purusha from which a person and his or her line is descended. Sudras are said to come from the feet.

In the Hindu Rig-Veda, the dvijas (twice-born) are identified as members of the Brahman, Kshatriya, and Vaisya castes. At about twelve years of age, members of these castes underwent a ceremony that made them “twice-born,” and they were thereafter permitted to study the Vedic scriptures. The Sudras were not dvijas and therefore were not allowed to study the Vedas. Such study usually consisted of listening to recitations or readings of the Vedas because the very sounds were believed to have religious power. Some ancient legal books report that Sudras caught listening to Vedic recitations had molten lead poured into their ears. A Sudra could also have been forced to drink boiling oil if he or she claimed to have taught someone something learned from the Vedas.

The ancient Hindu Laws of Manu discusses castes in great detail. This text gives names to the offspring of unions of men with wives of the different castes and to those born to unmarried parents. The Chandalas were produced by the union of a Sudra father and a Brahman mother. A Nishada (or Parasava) was produced by a Brahman father and a Sudra mother. A Sudra father and a Vaisya mother produced an Ayogava. A Sudra father and a Kshatriya mother produced a Kshattri. In addition the son of a Sudra man by a Nishada woman was identified as a Kukkutaka, among the many such designations outlined by the Laws of Manu.

The powerless Sudras were assigned to the rank of servants in India, and most service and menial jobs became their duties. According to the Laws of Manu, a Sudra faced with starvation could engage in handicrafts. However, the best way of life for a Sudra was to serve a Brahman, because this was the best occupation and prepared one for the next life. A Sudra is unable to lose caste, being already at the bottom; however, Sudras can prepare for the next world by imitating the virtuous.

Although Indians traditionally organized people into four major, rigidly defined social classes or castes, contemporary Indian society includes several thousand subcastes called jati, meaning “birth,” “lineage,” or “race.” Most jati probably developed from hereditary occupational practices. Many jati are regionally based. Some jati groups comprise only a few hundred families, while others may
include thousands of families. Usually these are endogamous status groups.

Another function of varna is that it creates a complex system of purity and impurity. The ritual purity one acquires at birth may be enhanced by the practice of rituals during life. The higher the caste, the purer are its members. However, the higher castes are also considered to face the grave danger of ritual contamination from members of the lower castes. Purity regulations codify many areas of Indian life, especially those involving intimacy, such as drinking, eating, touching, and marriage. According to the Laws of Manu, drinking from a vessel after a Sudra used it would cause spiritual pollution of members of the higher castes. Purification requires a three-day regimen of drinking water in which kusa grass has been boiled. In addition twice-born Indians are forbidden to eat food prepared by a Sudra because it is considered to be impure. If a Brahman died with Sudra food undigested in his or her stomach, that person would be reborn as a Sudra. Sudras were urged to fast and eat only the leftovers of the dvijas. To become Vaisyas in the next life, Sudras had to abstain from meat.

Practices regarding touch have remained a sensitive area. If a Sudra should accidentally touch someone of a higher caste, such as a Brahman, then the Brahman would consider himself or herself contaminated, and extensive rites of purification would be necessary to remove the stain. Marriage is permitted only between members of the jati of a particular varna. According to the Laws of Manu, mixed-caste marriages violate the cosmic law of dharma that orders the world. Such marriages would therefore cause chaos.

In Tamil-speaking areas of South India, the population is made up mostly of Sudras, with only a few Brahmans and almost no Kshatriyas or Vaisyas living in many areas. Tamil-speaking Sudras have developed practices unknown to the original caste system of northern India. Among the numerous rankings of agricultural Tamil, the success of many Sudras has in practice put them above other castes in wealth and power.

Discrimination on the basis of caste has been against the law in India since the country achieved independence from Britain in 1947. However, the Hindu system requires castes, so the lives of many Sudras in tradition-bound rural India have barely changed. Many still belong to agricultural jati in which they are landlords or members of particular skill groups, giving them an incentive to maintain the caste system.

In urban areas the pace of life makes it more difficult to practice caste discrimination. While discrimination still exists in many rural areas, it is breaking down in India's cities. Urban Sudras have been able to organize and use political power to advance the status of their caste. Their success has been limited, however, by their numerous jati and the continuance in many areas of Hinduism's varna belief. Long practice enforces personal and informal discrimination despite the laws, but in many areas prosperous Sudras are marrying into higher castes. When this occurs, Sudras often change their names to disguise their Sudra origin.

**SUEZ CRISIS**

The Suez Crisis of October 1956, which involved a coordinated attack by British, French, and Israeli forces on Egyptian positions in the Sinai Peninsula and along the Suez Canal, was a pivotal moment not only for interstate relations within the region, but also for interactions between the superpowers within the larger context of the cold war. Triggered by numerous factors and settled by an uneasy cease-fire, the Suez Crisis left a great deal of “unfinished business” on the table between Israel and the Arab States. It also saw the first full engagement of the United States into the region.

The political environment in the region had been deteriorating for an extended period prior to the actual invasion. Among the elements that contributed to this situation were: (1) the 1955 establishment of the Baghdad Pact between Turkey and Iraq; (2) the completion of an extensive arms deal between Czechoslovakia and Egypt; (3) the prospect of the sale of modern weaponry to Iraq and possibly to other future Baghdad Pact members; (4) the nationalization of the Suez Canal by Egypt in June 1956, which included provisions that excluded Israeli
shipping from passing through the canal and a blockade of the Gulf of Aqaba and Straits of Tiran (which cut off all shipping into Israel’s southern port city of Eilat); (5) increased incursions into Israel by Palestinian guerillas known as the fedayeen (whom Israel labeled as terrorists); and (6) the October 1956 expansion of the Syrian-Egyptian joint military command to include Jordan. As a result of these events, the Israelis believed that they were “under siege” and that action was needed.

For the Israelis, there were three main goals behind any action undertaken in late 1956: (1) the restoration of freedom of navigation through the Gulf of Aqaba and Straits of Tiran, (2) cessation of fedayeen raids, and (3) the elimination or reduction of the threat posed by the Egyptian army deployed in Sinai. The British and French were not happy with the situation either, but they were focused on the implications of Egypt’s nationalization of the Suez Canal and Nasser’s support for Algerian nationalists fighting against the French.

Although their motives were different, the three sides agreed that the situation was intolerable and action needed to be taken. In fact, the Israelis had considered taking unilateral preemptive action, but they were instead “invited” to participate in the action already being planned by the British and French. The timing of the operation was also influenced by perceptions that both the United States and the Soviet Union were distracted or involved with other things at the time, and that they would therefore not “interfere” with the operation. For the United States, 1956 was a presidential election year, and the British, French, and Israelis believed that the Americans would be wrapped up in their own electoral cycle, and that President Eisenhower would not risk his chances of winning re-election by getting involved in an international conflict. It was also believed that the Soviets had their hands full dealing with rising national sentiments in both Poland and Hungary.

The actual invasion of Egyptian territory by Israeli forces began on October 29, 1956. By November 7, a cease-fire was brokered. Part of the cease-fire agreement included the establishment of a peacekeeping force under the auspices of the United Nations. Known as the United Nations Emergency Force (UNEF), these troops were intended to serve as a buffer between Egypt and Israel. They were charged with ensuring that freedom of navigation throughout the Straits of Tiran was maintained, and that there would be no cross-border raids by guerrilla forces. These were two of the primary Israeli concerns that led to the outbreak of armed hostilities. UNEF also supervised the withdrawal of Israeli forces from Egyptian territory, a process that was completed by March 1957. UNEF remained deployed in the area until May 1967, when President Gamal Abdel Nasser expelled the force from Egyptian territory.

The Suez Crisis also had larger implications for the region and for the international system as a whole. For the first time, the United States was brought into the Arab-Israeli conflict, although the Americans tended to view the situation in terms of the larger cold war context. In early 1957, concerns about Nasser and Soviet influence in the region led the Eisenhower administration to formulate what would become known as the Eisenhower Doctrine. According to this policy, the United States would provide assistance, when requested, to any country in the Middle East threatened by international Communism. In this respect, the Eisenhower Doctrine set the stage for active U.S. involvement in the region.

SUFRAGE MOVEMENT, WOMEN’S
SEE Sufrage, Women’s; Women’s Movement.

SUFRAGE, WOMEN’S
With few exceptions, women were not allowed to vote before the twentieth century. In 1900, however, only twenty-five nations held regular elections for at least some of their political leaders, and only six recognized the right of suffrage for most of their adult male citizens. Several American states and territorial governments granted women voting rights between 1855 and the 1890s; Sweden and Great Britain offered a limited right in local elections to some women in the 1860s; but New Zealand in 1893 was the first to guarantee a national right of women’s suffrage. About two dozen European nations as well as Australia and Canada extended the right to vote to women by 1919. In 1920 the Nineteenth Amendment to the U.S. Constitution barred gender-based prohibitions of the right to vote in the United States. Other democracies recognized voting rights for women only after World
War II, France in 1944, Italy and Japan in 1945, and other nations still later, India (1950), Switzerland (1971), Portugal (1976), Taiwan (1996), and Kuwait (2005). In 1945 the newly established United Nations recognized "the equal rights of men and women" in its charter, and its 1948 Universal Declaration of Human Rights specified that "the will of the people shall be the basis of the authority of government; ... [as] expressed in periodic and genuine elections" and "by universal and equal suffrage." Moreover, the declaration continues, these rights and freedoms are to be honored "without distinction of any kind, such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status." At the beginning of the twenty-first century, more than half of all nations and approximately 60 percent of the world's population live under some form of electoral democracy; among these nations, the full recognition of women's voting rights has become a common baseline for assessing the presence of democracy.

The woman suffrage movement in the United States is commonly traced back to a women's rights meeting convened in Seneca Falls, New York, in 1848. This point of origin, although significant, overlooks the ways the idea of women's suffrage extends and gains much of its force from the principles of equality, consent, and liberty that emanate from democratic forms of government, however imperfect these forms or political practices may be at a particular time. For the democratic ideal that requires the equal treatment, consent, and empowerment of more than a select few within a society offers a suggestive logic supportive of efforts to include others, if not ultimately all persons, in the democratic process of self-governance. However self-evident this inclusionary logic may be to some, democratization is almost never self-executing or easy because most social relations in the world have been and remain ordered principally in nondemocratic ways.

EARLY HISTORY

From this perspective, the efforts of Margaret Brent, a Catholic immigrant to the colony of Maryland in 1638, offer the first instructive case of a woman who demanded full recognition of her right to vote along with her male peers. Brent was a prominent, unmarried property owner, businesswoman, and attorney in colonial Maryland. She also served as the legal executor of the estate of Maryland governor Leonard Calvert. Under the leadership of the Calvert family, Maryland was founded in the 1630s as the first American colony to recognize the freedom of religion. In 1645 the colony suffered extensive political and sectarian religious strife after Puritan militants invaded the colony, imprisoned several Catholic leaders, and plundered their estates.

Governor Calvert succeeded in defeating the militants in 1647, but he died the same year, leaving Brent to assume a leading role in restoring order within the colony. To aid her efforts, Brent in 1648 requested two votes in the Maryland colonial assembly. The first vote she claimed for herself, the second she claimed as the legal executor of Calvert's extensive property interests in Maryland. Brent's claims to a right to vote were rejected, but the assembly commended her critical contributions to the survival of the colony. Brent protested her exclusion from the assembly's proceedings and later elected to resettle in neighboring Virginia. Although Brent's attempt to secure her right to vote failed, historical records indicate that at least a small number of American colonial women—most likely all widowed or unmarried property owners—successfully asserted their right to vote in several colonial elections.

The subsequent democratic advances initiated by the American and French Revolutions in 1776 and 1789 supported similarly instructive associations between the principles carried by the democratic form and the advocacy of new women's rights, including the right to vote. On the eve of American independence, for example, Abigail Adams appealed to her husband, John Adams, then a Massachusetts delegate to the Continental Congress and later the second U.S. president. "Remember the Ladies," Abigail famously wrote, "and be more generous and favourable to them than your ancestors.... [For] if particular care and attention is not paid to the Ladies we are determined to foment a Rebellion, and will not hold ourselves bound by any Laws in which we have no voice, or Representation." (Abigail Adams to John Adams, March 31, 1776, Adams Family Papers, The Massachusetts Historical Society).

Although Abigail Adams failed in 1776 to convince her husband that democratic government required the consent of all, including women, the logic of her argument was repeated and became commonplace among subsequent advocates of women's suffrage reform, including the French revolutionary thinker Marquis de Condorcet in the 1790 essay "On the Admission of Women to the Rights of Citizenship." Ironically, the more radical French Revolution never yielded robust efforts to extend voting rights for French women—despite their critical role in national events. American women, by contrast, possessed the right to vote in New Jersey state elections from 1776 until 1807, when a state constitutional amendment limited the suffrage to white, adult males. In addition property-owed widows with school-age children were permitted to vote in local school board elections in Kentucky in 1838. These limited and highly exceptional American examples vividly demonstrate how little progress was made on effecting the idea of women's suffrage during the first half of the nineteenth century.
THE SENECA FALLS CONVENTION

Several propitious conditions in the 1830s and 1840s sustained the idea and hope for women's suffrage. The most important of these conditions was the emergence of more activist and organized antislavery and temperance movements in the United States. Women were core elements in both movements, and many in turn gained deeper commitments to the democratic principles of equality and liberty as well as invaluable experiences regarding the organizational mechanics and difficulties of social reform. Coincident with these movements, voting rights and mass forms of political participation expanded to include a greater portion of the adult male populations in the United States, Great Britain, and parts of Europe. Social reformers of all sorts were encouraged by these democratic developments, which paralleled new educational, economic, and social opportunities afforded to a small but growing number of women. The advances of this period, however, also made manifest to some the inequity and democratic contradictions of the continued exclusion of women from voting and other forms of public participation. U.S. women's rights advocates, such as Angelina Grimké and Sarah Grimké, initiated public discussions of these issues, which inspired wide public fascination, numerous critics, and a generation of future woman suffrage activists.

Against this historical backdrop, more than 300 women and men, including Frederick Douglass and other abolitionists, met in Seneca Falls in 1848. Inspired by the abolitionist movement, Quaker egalitarian ideals, and the Declaration of Independence, the organizers of this meeting (Elizabeth Cady Stanton, Lucretia Mott, Mary Anne McClintock, and others) proposed that the convention discuss the “social, civil and religious rights of women.” Attendees heard numerous speeches, but the most important was Stanton and Mott’s “Declaration of Sentiments,” which proclaimed “that all men and women are created equal” and that “it is the duty of the women of this country to secure to themselves their sacred right to the elective franchise.” Convention members vigorously debated the latter claim before they ultimately endorsed it and the declaration as a whole. With few exceptions, public reactions were hostile to the convention’s advocacy of woman suffrage, and many who endorsed its declaration publicly retracted their support. Over the next decade additional women’s rights conventions met, which along with new pro–women’s rights publications attracted greater public attention for the movement and strengthened a small but activist network of leaders that included Stanton, Susan B. Anthony, Paulina Wright Davis, and Lucy Stone. Despite these developments, suffragists garnered no additional political advancements before the U.S. Civil War, although Kansas extended school board election voting rights to women in 1861.

THE POST–CIVIL WAR PERIOD

The conclusion of the Civil War opened new opportunities for political, economic, and social change in the United States. Foremost among these widely anticipated changes were the amendments required in the U.S. Constitution and most state constitutions. Woman suffrage leaders appealed directly to those who possessed the most influence over these expected constitutional changes: members of Congress, state legislators, party leaders, and abolitionist groups. Suffrage leaders also founded the American Equal Rights Association (AERA), which jointly promoted women and African American rights within a single “human rights” agenda framed, according to Anthony, by “the farthest bound of the principle of the ‘consent of the governed.’” At both the state and federal levels, however, not a single women’s suffrage amendment or popular referendum won political support. Stanton moreover ran (although she was not permitted to vote) for a U.S. House seat in New York in 1866. She lost, receiving only 24 votes of 22,450 cast. The political weakness of the woman suffrage movement also was evidenced by the fact that the Fourteenth Amendment to the U.S. Constitution (ratified in 1868) formally recognizes each state’s power to limit the right to vote to “male inhabitants,” an engendered description of the right to vote not present in the original U.S. Constitution.

Some women suffragists found partial consolation in the language of the Fifteenth Amendment of the U.S. Constitution (ratified in 1870) because it used gender-neutral language to prohibit states from denying or abridging voting rights of U.S. citizens based upon race, color, or previous condition of servitude. Other activists, such as Stanton and Anthony, were embittered and radicalized by their political failures, and they withheld support for the ratification of the Fourteenth and Fifteenth Amendments, thereby severing themselves from other suffrage supporters and many of their former abolitionist and Republican Party allies.

After 1868 fissures among woman suffrage advocates grew more prominent. Stanton, Parker Pillsbury, and Anthony founded a new women’s newspaper, abandoned the AERA, and led efforts to create the National Woman Suffrage Association (NWSA). Under the leadership of Stanton and Anthony, the NWSA focused on securing a national constitutional amendment, but the two advocates and others aligned with them increasingly became involved in the promotion of other social reforms too. Their efforts won praise from some, greater opposition from entrenched and popular social interests, and no immediate political results related to the suffrage issue. For example, between 1869 and 1889 no women’s suffrage constitutional amendment won approval in either branch of Congress. In addition to its constant lobbying of members of Congress, the
NWSA experimented with other constitutional reform tactics, which included civil disobedience and the federal judiciary. The latter hope was encouraged by a novel and expansive interpretation of the Fourteenth Amendment’s protections of the “privileges or immunities” of American citizens. In 1872 Anthony and other women were arrested for attempting to vote in state elections. Their trials attracted considerable media attention for the idea of women's suffrage and ultimately the desired opportunity to press their claim before the U.S. Supreme Court. In Minor v. Happersett (1875), however, the Court determined that the term citizens in the Fourteenth Amendment did not grant women the right to vote.

Woman suffrage advocates not aligned with the NWSA formed other organizations, including the American Woman Suffrage Association (AWSA). Established in 1869 and led by Henry Ward Beecher, Henry Blackwell, Stone, and others, the AWSA published a weekly national newspaper, the Woman’s Journal. Unlike the NWSA, its principal focus was state and local suffrage reform movements; yet the record of political achievements also was limited over the next twenty years. Despite sustained organizational efforts, most states did not vote on suffrage amendments or referenda; where they did, the male electorate rejected women’s suffrage in Kansas in 1867, Nebraska in 1871, Michigan in 1874, Colorado in 1876, Oregon in 1884, Rhode Island in 1887, and Washington in 1889. Several successes were sufficient to encourage reform efforts in other states, yet only four western American territorial states granted women full voting rights: Wyoming (1869), Utah (1870), Washington (1883–1887), and Montana (1887). In 1867 Michigan women taxpayers received a limited right to vote in school trustee elections; women in Kansas received full voting rights in municipal elections in 1887. By 1889 American women could vote in school-related elections in about a dozen states and territories.

THE TWENTIETH CENTURY AND THE NINETEENTH AMENDMENT

In 1890 the NWSA and AWSA merged into the National American Woman Suffrage Association (NAWSA). Like its predecessors, the new organization continued its lobbying and grassroots efforts, but it too achieved mixed political results. Over the next two decades additional states granted women's suffrage in school, municipal, and tax-related elections, but only five states—Wyoming (1890), Colorado (1893), Utah (1896), Idaho (1896), and Washington (1910)—recognized a woman’s right to vote in all elections. Despite persistent opposition to the idea of women’s suffrage, progressive social, economic, and political conditions in the United States and Europe accelerated the woman suffrage movement in the 1910s. President William H. Taft spoke to the 1910 NAWSA annual convention. Although he did not endorse women’s suffrage, his presence at the meeting was perceived as an endorsement by NAWSA members and the media. In 1912 former president Theodore Roosevelt publicly supported woman suffrage, and the social reformer and NAWSA activist Jane Addams seconded Roosevelt's nomination for president at the 1912 Progressive Party convention. The Democrat Woodrow Wilson won the presidency in 1912 without supporting woman suffrage, but Progressive Party legislators in Illinois proved critical for the passage of legislation in 1913 that recognized women's voting rights in presidential and municipal elections. By mid-decade about one-third of American states fully recognized a woman’s right to vote, but only five national democracies did: New Zealand (1893), Australia (1902), Finland (1906), Norway (1913), and Denmark (1915).

World War I (1914–1918) and its aftermath corresponded with renewed efforts by national woman suffrage organizations and a further consolidation, especially in Europe, of the relationship between democracy and recognition of women's voting rights. The United Kingdom recognized the right for women thirty years or older in 1918; Austria, Germany, Hungary, Ireland, and Poland recognized national rights of women's suffrage in 1918, as did Belgium, the Netherlands, and Sweden in 1919. In the United States the NAWSA and the Congressional Union worked to win congressional approval of an amendment to the U.S. Constitution. In addition to lobbying members of Congress and President Wilson, these organizations effectively orchestrated mass marches, petition campaigns, and political candidate endorsements designed to exert electoral pressure on the national political parties and those running for office. In 1917 the National Woman’s Party, led by Alice Paul and Lucy Burns, supported widely publicized protests and acts of civil disobedience in which some were arrested and imprisoned for chaining themselves to the White House fence. Publicly President Wilson remained uncommitted, refusing to endorse constitutional amendment efforts in Congress. But by January 1918 Wilson’s conceptions of a more peaceful and democratic postwar world were clear, and he argued before the U.S. Senate on September 30, 1918 that a women's suffrage amendment was “clearly necessary to the prosecution of the war and the successful realization of the objects for which the war is being fought” (Cong. Rec). The U.S. House of Representatives endorsed the amendment by the required two-thirds majority, but the U.S. Senate stalled the amendment until June 1919, when it too passed the Nineteenth Amendment. By August 1920 three-quarters of the states required by the U.S. Constitution had ratified the Nineteenth Amendment.

SUGAR INDUSTRY
Sugar has been an important commodity historically due to a variety of factors, including the human appetite for sweet foods and drinks, the complementarity that sugar brings to the other flavors in food, its preservation and fermentation properties, and the calories it provides. Sugar (or more precisely sucrose) was first prepared in India. It was brought back to the Western world by the Greek conqueror Alexander the Great in 325 BCE. Trade in sugar was further expanded in the Mediterranean region by the Arab conquest of the sixth century CE. Improvements in the crystallization process expanded the sugar trade (especially in the form of molasses) in the twelfth century. However, the limited supply of sugar in the international market caused refined sugar to be relatively costly until the production of sugar by European colonies in the Americas grew after 1700. This expansion, coupled with improvements in refining technologies that reduced unwanted tastes in the sweetener, caused sugar to replace other sweeteners such as honey, becoming the dominant sweetener over time. While demand for sugar remained unaffected by the introduction of non-nutritive sweeteners, in the early twenty-first century the dominance has been challenged, particularly in the United States, by high fructose corn syrup (HFCS). The competition between sugar and HFCS raises several policy questions.

HISTORICAL TRADE PATTERNS
The fact that the expansion of production and trade of sucrose was largely linked to the European colonization of the Americas had significant implications for the institutional arrangements in the international sugar market in place at the beginning of the twentieth century. Specifically colonization of the Americas as well as other parts of the globe in the eighteenth and nineteenth centuries was at least partially driven by economic considerations of the countries involved. Restrictions were placed on the countries with which colonies could trade. Raw goods produced in the colonies were required to be sold in the mother country and significant import restrictions existed to encourage the purchase of manufactured goods to each respective European power. This enabled the European powers economic benefits from the colonization of the New World.

Another byproduct of the rise of sugar in European colonies in general and in the Americas in particular was the linkages between sugar and slavery. As described by B. W. Higman in his 2000 article for Economic History Review, the rise of the sugar economies in the seventeenth through the nineteenth centuries in the Caribbean has been labeled as “The Sugar Revolution.” This revolution has been associated with several empirical facts, including the increased importance of monoculture, the replacement of small farms with plantations, and the increased use of black slaves. The movement toward monoculture and increased farm size has proven not to be unique to sugar; however, certain characteristics of sugar production may make the crop more susceptible to the establishment of plantations. The relationship between sugar and slavery may be more systematic. The exact reason for this linkage is unclear. One explanation for this linkage could be the presence of scale economies. In 1977 Mark Schmitz found evidence of significant economies of scale in Antebellum sugar production in Louisiana, which used slavery. Further evidence of the economies of slavery-based agriculture can be found in Robert Fogel and Stanley Engerman’s 1977 work.

The elimination of slavery in the colonial powers and the United States in the nineteenth century changed the institutions in the labor relationship. Slaves were replaced with contract labor, but the use of contract labor in the sugar plantations implied a radical change in the source of that labor. Before 1770 one-half to two-thirds of the contract labor destined for the British Caribbean and other North American colonies came from Europe. However, the contract labor for the sugar plantations was predominantly non-white. This shift also implied significant
changes in the terms of the labor contract. In addition, the reduction of the availability of contract labor from countries such as India undoubtedly accelerated the introduction of labor-saving technology to the industry.

The entanglement of European powers in the trade of sugar also contributed to the first significant alternative sweetener. The British blockade of European ports during the Napoleonic wars led to the development of a viable sugar beet industry in France. In the twenty-first century sucrose from sugarcane and sugar beets share the global market for refined sugar. The expansion of sugar beet production in the second half of the nineteenth century followed a host of factors—including the abolition of slavery in Britain and France and the expansion of grain imports from Russia—that reduced the profitability of grain crops in Europe.

The decline in the price of sugar had two divergent impacts on the economy. First, lower sugar prices reduced the cost of a primary input for a variety of industries (i.e., bakeries, breweries, and the makers of jams). Second, lower sugar prices impoverished producers in the colonies. The same policy scenario applies to the present-day United States. Sugar tariffs pit the interest of sugar producers against the interests of confectionary manufacturers. The ultimate dispensation of this debate depends on the relative political power of each sector through rent-seeking behavior. One response to the declining sugar prices both in the nineteenth and in the twenty-first centuries is the establishment of import tariffs or quotas to increase the domestic price and, thereby, protect domestic sugar producers.

MODERN SUGAR MARKET

Despite the end of European colonial rule, many of the tariff agreements continue to follow the trade patterns established in colonial times. With the emergence of the European Union (EU) as an economic union in the closing years of the twentieth century, agricultural policy coalesced into the Common Agricultural Policy (CAP) of Europe. The CAP established a system of tariffs to protect domestic producers from foreign competition. Historically, African, Caribbean, and Pacific (ACP) sugar producers were given access to the European market under the CAP through the Sugar Protocol of the Lomé Convention and its successor the Cotonou Agreement.

At the beginning of the twenty-first century, most countries that support their internal sugar price use a form of the tariff rate quota (TRQ) which is allowed under the Uruguay Round Agreement on Agriculture. The TRQ is a system of two tariffs. The first tariff allows the sale of a fixed quantity (or minimum access) of a commodity at a lower or first tier tariff. Any quantity of that commodity imported above this fixed quantity is charged a higher (typically prohibitive) tariff. Given that the second tariff level is prohibitive, the country can increase the price received by domestic producers by reducing the fixed quantity imported under the first tier tariff. This is the policy instrument used by both the United States and the EU to increase the price of sugar for their respective producers. However, apart from supporting domestic producers, the TRQ gives countries in the EU a mechanism to honor its commitments to the ACP. Specifically, former colonies can be allocated portions of the minimum access quantity, in essence giving ACP countries access to a higher internal price of sugar at a low tariff rate. The United States allocates its first-stage quota in a similar way to a group of forty countries.

Apart from its grounding in historical trade patterns, the international sugar market is also affected by a myriad of regional and global trade agreements. Regional trade agreements involve a small number of countries in the same geographic region. In this context, the agreements forming the EU are a regional trade agreement. Other regional trade agreements include the North American Free Trade Agreement (NAFTA) and proposed trade agreements such as the Free Trade Area of the Americas (FTAA). The effect of each of these trade agreements on sugar markets is dependent on the role sugar plays in each group of economies.

An example of the ambiguous role regional trade agreements play in the sugar market can be found in NAFTA. As discussed, the sugar price in the United States is protected by a system of tariffs. From this perspective both freer trade with both Canada and Mexico raise critical issues. First, while Canada does not pose a direct threat to the U.S. sugar industry from production, the TRQ on sugar prohibits pass-through imports of sugar into the United States through Canada. However, NAFTA still allows for the importation of sugar containing products from Canada, increasing the competition for confections in the United States and reducing the demand for sugar. For example, lower sugar prices contributed to Kraft Foods’ decision to move the production of Life Savers candy entirely to Canada in 2003.

A different set of problems was raised by the potential effects of Mexican sugar production on the U.S. sugar market. Mexico’s government has historically been involved directly in its sugar industry through its ownership of its sugar mills and other policies but had divested these holdings as a part of its economic liberalization program in the late 1980s. In recognition of the potential competition from Mexico, NAFTA includes specific provisions governing Mexico’s access to the U.S. sugar market. Many of these provisions are concerned with Mexico’s status as a net sugar producer. Specifically, since Mexico imports sugar and other sweeteners, the domestic produc-
ers wanted to be protected from pass-through sugar (i.e., sugar purchased at lower world market prices for sale at protected U.S. prices). Hence, Mexico was granted duty-free access to the U.S. market for 7,258 metric tons of sugar. If Mexico obtained the status of a net sugar-surplus producer, the quota would be expanded to 25,000 metric tons in years 1 to 6 and 250,000 metric tons in years 7 to 15. Some controversies have arisen in the implementation of these provisions. Specifically, the original provisions were restricted to becoming a net sugar-surplus producer, ignoring the potential impact of alternative sweeteners such as HFCS. This raised the possibility of substituting HFCS for sugar especially in the manufacture of soft drinks to enhance Mexico’s net surplus of sugar.

In the mid-2000s the URRA of the WTO remains the most relevant multilateral trade agreement facing the international sugar market. Within this context, it is important that the TRQ format of the EU and the United States is the sanctioned agricultural policy and thus completely legal under the WTO. The primary question is then whether significant changes to these accepted instruments will occur in the Doha round of WTO negotiations started in 2001. At its inception, increases in market-access were primary to the Doha round discussion on agricultural trade. One idea is to increase market access by expanding the minimum access portions of the TRQs.

SUGAR PRODUCTION

Various domestic factors affect the production of sugar and institutions within the U.S. sugar market. As discussed, sugar prices in the United States are supported by a TRQ. Adding a layer of complication, the government supports the domestic price of sugar by providing a non-recourse loan for raw sugar at 18 cents per pound and refined sugar produced from sugar beets at 22.9 cents per pound, according to 2002 statistics (Haley and Suarez 2002). If the market price falls below 18 cents per pound, producers (or more accurately sugar mills) store their raw sugar and receive a loan from the government of 18 cents for every pound of raw sugar placed in storage. If the market price for sugar rises over 18 cents per pound plus any interest accrued, they take the sugar out of storage, sell it at the prevailing market price, and repay the loan. However, if the market price for sugar does not exceed 18 cents per pound plus accrued interest during the marketing year, producers simply forfeit sugar in storage to the government in fulfillment of the loan. While the non-recourse loan program for sugar is typical for agricultural commodities in the United States, it is encumbered by the Dole Amendment, which requires the sugar program to be operated at no cost to the government.

Certain characteristics of sugar production have implications for vertical integration in the market channel for sugar. Sugar is produced from two different primary crops: sugarcane and sugar beets. While the end product (i.e., sucrose) is identical for each process, each crop implies a different market channel. The production of sugarcane typically occurs in tropical or subtropical climate zones. The stalks containing the sucrose are removed from the field for milling that produces a raw form of sugar that is relatively stable. The raw sugar is then later refined into table sugar, removing impurities that may affect the flavor. Technical considerations require that these mills be located close to production. When the stalks are harvested in the field the sucrose content of the sugarcane starts to deteriorate. Further, the sucrose content of standing sugarcane deteriorates after a freeze.

Following Coase’s paradigm (1937) that the boundaries of the firm are determined by the comparison of transaction costs with the diseconomies of scope, the technical characteristics of sugarcane are conducive to the vertical integration of production of processing of sugarcane. Specifically, in Coase’s paradigm the boundaries of a firm are dictated by a comparison of transaction costs and diseconomies of scope. In this case transaction costs include the possibility of using a thin market to extract monopolistic rents while the diseconomies of scope involve the economic costs of carrying out an activity that is outside of the firm’s specialization. In the case of sugarcane, the potential deterioration of quality gives rise to the possibility of monopolistic rents. The possible economic losses of economic rents more than offset the economic costs of diversification into processing facilities. Viewing the transaction from the other side, the diversification into sugarcane production insures a steady supply of sugarcane into the future, reducing the risk of investment.

Production of sucrose from sugar beets does not face the same climatic constraints as sugarcane. Further, the sucrose content of sugar beets is more stable than sugarcane, extending the period for the extraction of sucrose from sugar beets. Thus sugar beet producers have less impetus for vertical integration than producers and processors of sugarcane.

Finally, any discussion of the sweetener markets, particularly in the United States, is not complete without reference to HFCS. HFCS is a liquid sweetener derived from corn that can be used in production of soft drinks and other industrial uses. It is typically conceded that sugar tariffs in the United States provided the incentives for the commercial development of HFCS production. However, while HFCS is a perfect substitute for sugar in many applications, it lacks the baking quality to replace sugar completely. The interaction between sugar and HFCS prices is then dependent on the saturation of specific sweetener markets. For example, HFCS is easily used in the production of soft drinks and, because it is typically

220 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
priced lower than sugar, dominates the sweetener market for this market. Thus the relationship between HFCS and sugar prices depends on the substitutability of the use at the margin.

SUICIDE
Suicide can be the outcome of an individual’s difficult and stressful experiences or a response to an unbearable situation. Sometimes suicide is complicated by drug and/or alcohol use. The scope of suicide includes all ages, classes, races, and sexes, although some groups are at more risk than others. Children or family members of those who have attempted or completed suicide are more likely themselves to attempt or complete suicide, as suicide has a ripple effect and can convey the idea that self-destruction is an acceptable solution to distress. Casualties of suicide, or those left behind, experience traumatic grief, guilt, shame, stress, and self-doubt—sometimes keeping them from speaking of the event at all. Statistics of suicide are underrepresented and not always reliable because the action can be classified in some other way; legally, suicidal components must be established beyond a doubt. Additionally, it is sometimes difficult to categorize the intentionality of death.

Suicide rates are higher for those who suffer from depression or other psychiatric problems; use drugs or alcohol when depressed; suffer from physical, especially irreversible, illness; are divorced; have lost an important relationship through death or breakup; and live in certain areas. War combatants also face a high rate of suicide because of post-traumatic stress disorders. People with HIV/AIDS are at risk, with the decision of suicide based on the fear of loss of function or increase in suffering and the feeling of being isolated. In “suicide by cop” incidents, an armed suicidal individual forces a law officer to use deadly force resulting in death. Individuals name various other reasons for suicide, including as a means to reunite with the dead, a means to ensure rest and refuge, a way to take revenge, and a penalty for failure.

DURKHEIM’S STUDIES
In 1897 the French sociologist Émile Durkheim (1858–1917) conducted a study of suicide in France. He found lower suicide rates among women, Catholics, Jews, and married people and higher rates among men, Protestants, wealthy people, and unmarried individuals. Based on the data, he argued that categories of people with strong social ties had low suicide rates, and that categories of people with the lowest social integration had the highest suicide rates. Durkheim believed that too much or too little integration or regulation (cohesion) was unhealthy for society and accordingly established four conditions that can lead to suicide: (1) altruism, or too much integration, a willingness to sacrifice the self for the group's ostensible interest (e.g., suicide bombers); (2) egoism, or too little integration (e.g., those not bound to social groups left with little guidance); (3) fatalism, or too much regulation with no perceived way out of a situation.
Suicide

(e.g., slaves); and (4) anomie, or too little regulation and no fulfillment of needs (e.g., those coping with the death of a spouse, economic depression, institutional failure, or wealth insufficient to provide happiness). Durkheim focused on anomie as an unhealthy and destructive pathological state for society, resulting in a “milky-way-galaxy” of choices for normative behavior (read “normlessness”) and a lack of social regulation.

AMERICAN DEMOGRAPHIC DATA
In the United States, suicide ranks eleventh on the list of causes of death. Suicides occur most often among white males, and the rate increases with age; older white males have the highest suicide rates in the nation. Females and nonwhite males reach their peak for suicide vulnerability earlier in adult life. Suicide is the third leading cause of death in the age group fifteen to twenty-four. Bad economic times are usually associated with an increase of suicide rates. Rates for Native Americans are the highest of any ethnic population in the nation.

Suicide rates tend to be higher in areas where people live far apart from each other; more densely populated states have lower suicide rates. Accordingly, the highest suicide rates are in the western states, with Wyoming and Alaska at the top of the list, although California is ranked as having one of the lowest rates. The middle and eastern states are ranked lower in suicide rates than the western states (with the District of Columbia and Massachusetts as the lowest), although Vermont, West Virginia, and Oklahoma are ranked as high. Most of the New England states are ranked as having the lowest rates of suicide.

SUICIDE AMONG THE ELDERLY
Since 1990, in the United States there has been an increase in suicide rates in individuals eighty-five years or older, although suicide in the elderly does not elicit the same response as it does in younger individuals. Elderly individuals are more likely to be socially isolated for a longer time before death and are more likely to experience physical illness, other sources of distress and depression, and loss of relationships, making them at higher risk for suicide. Elders are less likely to give warning signs of suicide.

TEEN SUICIDE AND THE FAMILY
Since the 1980s the general incidence of suicide has increased in the United States; the rate for those between the ages of fifteen and twenty-four has tripled. Although suicide among adolescents is seriously underreported, researchers generally consider it to be the second- or third-most common cause of death in that group. More than eight out of ten kids who threaten suicide attempt it; females make more suicide attempts, although more males complete suicide, with firearms or explosives the most common method of self-destruction. Half of all children who have made one suicide attempt will make another, sometimes as many as two a year until they succeed. The majority of suicide attempts are expressions of extreme distress and not merely bids for attention; this distress is often related to others prior to suicide. Additionally, some children who take their own lives are indeed the opposite of the rebellious teen. They are anxious, insecure kids who have a desperate desire to be liked, to fit in, and do well. Their expectations are so high that they demand too much of themselves, thereby condemning themselves to constant disappointment. A traumatic event (such as the loss of a valued relationship or a change of residence), which can seem minor viewed from an adult perspective, is enough to push children and adolescents over the edge into a severe depression. Alcohol and drug use are associated with heightened suicide risk in youth.

The role of the family is also a variable in teen suicide. Two-thirds of suicidal teens report poor relationships with their parents. Increased levels of suicidal behavior in adolescents is associated with certain family characteristics: rigid rules, poor communication, overbearing parents, and long-term patterns of family dysfunction such as alcoholism and mental illness.

PHYSICIAN-ASSISTED SUICIDE
In some cases an individual may be too incapacitated by illness to end his or her life without assistance. The ethics of physician-assisted suicide, or euthanasia, has been the subject of vigorous debate. Active euthanasia refers to direct action being used to end a life; passive euthanasia refers to not taking steps to prolong life or “letting die.” Some argue that active euthanasia respects the principle of individual autonomy and the right to self-determination, that its foremost concert is the patient's well-being, and that it adheres to the physician's Hippocratic Oath to do no harm, where doing no harm means alleviating pain and respecting the wishes of a rational person. Many argue that a decision to kill oneself with the assistance of a physician is a private choice that society has no right to regulate; others argue that assisted suicide threatens the moral foundations of society.

INTERNATIONAL DEMOGRAPHIC DATA
Suicide rates vary from nation to nation, with Belarus, Estonia, Hungary, Kazakhstan, and the Russian Federation having the highest suicide rates in the world. Suicide rates for men are substantially higher in all countries and are also high for indigenous populations who have been exploited, discriminated against, and deprived
of their previous cultural existence. China is undergoing a national suicide crisis, with 21 percent of the world’s population, 44 percent of the world’s suicides, and 56 percent of the world’s female suicides. Those in China at a higher risk of suicide live in rural areas or areas where the government has policies that have increased stress through the disruption of traditional family patterns. Some argue that this level of suicidal behavior has changed attitudes in China about suicide, with self-destruction coming to be seen as an acceptable action.

OTHER MANIFESTATIONS OF SUICIDE
Suicide can also occur as a group response to extreme situations, notable examples being the mass suicide at the Masada fortress in 73 CE by besieged Jews choosing death over defeat by the Romans; the Jonestown cult’s mass murder-suicides in Guyana in 1978; and the Heaven’s Gate cult suicides in southern California in 1997.

Suicide bombings by terrorist groups became a phenomenon in the late twentieth century. Terrorism constitutes random acts of violence or the threat of such violence as a political or religious strategy, and suicide bombing is one of these strategies. The attacks of September 11, 2001, show how self-destruction can be used as a weapon.

The act of suicide has been interpreted in many ways and given various meanings. In Christianity and Judaism, suicide is sinful and forbidden. Historically, many societies have viewed suicide as a crime and have enacted laws to regulate the act and punish those who attempt it. Those who attempt or commit suicide have often been seen as psychotic or mentally ill; by contrast, in some cultures suicide is viewed as an honorable and glorious death. Some approve of suicide when it is seen as the only option left to alleviate pain and suffering from severe illness. Freud understood suicide as a drive or death instinct; from an existentialist standpoint, suicide removes the necessary choice for authentic existence.

SUICIDE BOMBERS

A suicide bomber (or suicide attacker) is a person who participates in a suicide attack. Boaz Ganor, the cofounder of the International Policy Institute for Counter-Terrorism, has defined a suicide attack as one whose success depends on the death of the person or persons who carry it out. Suicide attacks are one of the tactics employed by terrorists, and since the early 1980s such attacks have become familiar worldwide, having been adopted by some thirty-two terrorist organizations and groups in twenty-eight countries.

The increasing use of suicide attacks by terrorist organizations is explained by the strategic and tactical advantages of such attacks:

1. The bombers themselves plan and carry out the attacks according to circumstances, and, because they operate as “smart bombs,” they can delay or cancel an operation if necessary.
2. The attack plan is relatively simple, since there is no need for an escape route.
3. The suicide bomber is a threat to morale and has a significant psychological effect on the target population.
4. The victimized population feels it is facing an enemy who does not budge from death, which in turn leads this population to pressure its government into negotiating with the terrorist organizations.
5. Attacks are also used to make the communities that support the terror organizations appear stronger and more powerful. This implants the idea that such attacks are the best way to fight a more powerful enemy.
6. Suicide attacks cause more casualties than any other types of terror attacks. For example, between 1982 and 2005, the average number of fatalities in shooting attacks worldwide was 3.2, bombing attacks killed an average of 6.92 persons, and suicide attacks killed an average of 81.48.

Historically, suicide attacks predate the modern period. The Moslem Hashashin of the late Middle Ages used this tactic, as did the Sulu who attacked the Spanish colonialists in the Philippines in the eighteenth century. In modern times, the Japanese kamikaze pilots used suicide attacks against the Allied fleet during World War II. From the first attack on October 25, 1944, until the last one on August 15, 1945, kamikaze pilots carried out more than 2,500 suicide attacks.

The first modern terrorist organization to employ suicide bombers was Hezbollah, an Islamic Shiite group based in Lebanon, which attacked the American Embassy in Beirut on April 18, 1983. On October 23, 1983, they attacked again, this time targeting the barracks of American and French soldiers. These attacks caught the attention of the entire world, not only due to the high number of victims (300 killed and 96 wounded), but also because of the consequent withdrawal of the multinational peacekeeping force from Lebanon. According to Robert Pape, a political scientist at the University of Chicago who has made an extensive study of suicide terrorism, this encouraged other organizations to adopt the use of suicide bombers, and throughout the 1980s other guerrilla groups used them against Israeli forces and their allies in Lebanon (2003, 2005).

The Liberation Tigers of Tamil Eelam (LTTE) in Sri Lanka have used suicide bombers more often than any other group. Between 1987 until 2006, they perpetrated over 200 suicide attacks. The frequent use of suicide bombers forced LTTE to adapt and develop the tactics of its attacks, which have ranged from simple attacks on military and civilian targets to more sophisticated attacks on the Sri Lankan Navy and Air Force.

In the late 1990s, and even more so in the early 2000s, other terrorist groups started to employ suicide bombers. During this period, most of these terrorist groups were concentrated in the Middle East region. Groups such as the PKK (Kurdistan Workers Party) in Turkey, the GIA (Armed Islamic Group) in Algeria, and the Egyptian Islamic Jihad used suicide bombers briefly during their struggle against state governments. The Palestinian organizations, however, are the only ones in the region to use this tactic for a long period of time. The first suicide attack in Israel was carried out by Hamas in April 1993, and over the years other Palestinian factions, such as Palestinian Islamic Jihad and PFLP (Popular Front for the Liberation of Palestine), have perpetrated many more attacks, with the peak coming in 2002. During al-Aqsa Intifada (2000–2005) the Palestinian factions carried out 145 suicide bombings. Following the beginning of the second Russia-Chechnya war, Chechen terrorist groups also began to use suicide bombers against the Russian Army, both in Chechnya and in Russia itself.

The group most closely identified with suicide bombings involving a large number of victims, however, is al-Qaeda, whose attacks on the World Trade Center in New York and the Pentagon in Washington, D.C., on September 11, 2001, killed nearly three thousand people. This attack is considered the most deadly suicide attack to date. Moreover, since the American-led coalition troops invaded Iraq in March 2003, al-Qaeda suicide bombers have attacked them repeatedly.

One of the most interesting features of suicide attack in modern times is the large percentage of women used as
suicide bombers. Groups such as PKK, and various Chechen factions, have used mostly women for suicide missions, whereas LTTE and Palestinian organizations have used both men and women. The use of women in such missions stems from the operational advantage of using women, who are considered less likely to be terrorists. In addition, in traditional cultures, women are not obliged to undergo security inspections, so they can often get closer to the target of attack more easily. The use of women in these missions has been justified by various claims, ranging from sex liberation and equal rights in nationalistic groups to religious justifications in the case of religious terrorist groups. However, many believe that these women have been forced to participate in suicide bombing against their will.

Car, truck, motorcycle, and boat bombs are all operational variations of the suicide attack. In each case, a vehicle filled with explosives and detonators is driven up to or rammed into the target. The “bag bomb” is carried to the scene of an attack, as is the more frequently used explosive belt. Packed with explosives and scrap metal to increase the damage when the wearer detonates it, an explosive belt has been used in 46.2 percent of terror attacks, while car and truck bombs have been used in 37.7 percent (Database on Suicide Terrorism 1982–2003). The choice of tactics depends on the surroundings, so that Hezbollah has generally used car and truck bombs to attack Israeli army convoys and installations, while LTTE has crashed boat bombs into Sri Lankan military vessels.

Suicide attacks have led to interdisciplinary studies investigating the motives behind them. The first attempts by researchers to explain the suicide bomber phenomenon, in the early 1990s, concentrated on the personal and socio-environmental motives of the individuals involved. More recently, however, the focus has shifted to the motives of the organizations. The increase in terrorist attacks carried out by organizations with a network structure, like al-Qaeda, has led researchers to focus on the immediate environment of the suicide bomber and the social network in which he operates. As a result, the spotlight is now on the dynamics within the social network, and on the effect of this network on the bomber’s decision to carry out an attack.

In addition to scientific research, which concentrates on analyzing the phenomenon of suicide attacks, there are a growing number of attempts to analyze the cultural motives behind the bombers themselves. The most widely known such attempt is the movie Paradise Now (2005), directed by Hany Abu-Assad, in which two brothers decide to sacrifice themselves as suicide bombers but are unable to follow through with their plan. These attempts have therefore been criticized as glorifying suicide bombers and not giving adequate attention to the perspective of the victims of suicide attacks.

**SUN YAT-SEN**

**1866–1925**

Born into a peasant family in Canton (Guangzhou), raised in Hawaii, and educated at colleges in Hawaii and Hong Kong, Sun Yat-sen (Sun Wen or Sun Yixian or Sun Zhongshan) played a key role in the overthrow of China’s Qing or Manchu dynasty (1644–1911), in the politics of the early Chinese Republic, and in the shaping of post-1949 regimes in Beijing and in Taipei. Sun came to be venerated in Taiwan as the “father of the nation” (guofu) and in the People’s Republic of China as a “pioneer of the revolution” (xianxinge). The cult of Sun seems to be one common denominator across the hostile Taiwan Strait. Retreating to Taiwan after his defeat in the civil war, Chiang Kai-shek (Jiang Jieshi, 1887–1975) legitimized his Guomindang (Nationalist Party) by mythologizing Sun. Beijing stresses Sun’s anti-imperialist campaign and his cooperation with Soviet Russia and the Communist Party. Such accolade is not shared by Western scholars, who have tried to demythologize Sun. Marie-Claire Bergère, for instance, dubs Sun “a traveling salesman of the revolution” (1998, p. 139), hardly present at the countless late Qing uprisings as he shuttled among nations to raise funds from overseas Chinese communities and foreign sources. It is telling, nevertheless, that Sun was from coastal China, which was long exposed to foreign influence, and that overseas Chinese were considered the “mothers of the revolution.” Modernization in China has invariably followed the pattern of spreading from coastal
areas inland, with Sun as an early symbol for what has continued into the twenty-first century.

In the chaotic times of the late Qing and early Republic, Sun, above all else, emerges as a paragon of revolution not necessarily because of his leadership in uprisings and politics but because of his writings. *The Three Principles of the People* is a compilation of his speeches, the 1924 version rendered definitive by his death more than anything else. It is an irony of history that this hodgepodge of ideas, by no means systematic and insightful, and derivative of American government apparatus, should become the sacred text for school children and university programs in Taiwan. Even the first line of Taiwan’s national anthem is a dull drone of “The Three Principles of the People.” On the other hand, *The International Development of China* (1922) was prescient in merging resources, as well as the economic zones revolving around major Chinese seaports, coincide with Sun’s blueprint. In the second phase, the groups opposed each other, participating in competitive and frustrating activities in which only the winning group could achieve harmony between opposing social groups, by introducing what he called “superordinate goals.” These goals are for both groups that can be achieved only through the cooperation of both.

This pursuit of specific goals sometimes results in conflict when a goal involves a valued resource that cannot be shared by competing subgroups. Hostilities are further exacerbated by self-categorization, which uses status or physical attributes to characterize “in-group” people (those like me) and “out-group” people (those not like me) for the purpose of treatment or differential allocation of resources. Such self-categorization occurs in (1) nations that compete for human and natural resources, (2) corporations that compete for customers and sales, and (3) other groups that are physically distinguishable and that compete for services and opportunities within the same society. This conflict between groups has no simple cause, and no totally effective solution. Nevertheless, Muzafer Sherif (1958) did demonstrate that it is possible to achieve harmony between opposing social groups, by introducing what he called “superordinate goals.” These are goals for both groups that can be achieved only through the cooperation of both.

In Sherif’s “Robbers Cave” experiment (so named for its site, Robbers Cave State Park in Oklahoma), boys attending a summer camp were, in the first phase of the study, divided into two groups that functioned independently of each other. In the second phase, the groups opposed each other, participating in competitive and frustrating activities in which only the winning group could have valued resources. The experiment demonstrated that (1) members developed unfavorable attitudes and deroga-

**SUPERORDINATE GOALS**

Social organizations are formed to accomplish specific goals, such as the acquisition of valuable resources necessary for the survival of the group in question. Crucial to this process is the recognition that some goals are more important than others, and that some people are better equipped than others to aid in their acquisition. As a consequence, hierarchies of both people and goals are frequently established to facilitate group functioning, whether that group is a small social unit such as a family, or a larger cultural, religious, or political group.

This pursuit of specific goals sometimes results in conflict when a goal involves a valued resource that cannot be shared by competing subgroups. Hostilities are further exacerbated by self-categorization, which uses status or physical attributes to characterize “in-group” people (those like me) and “out-group” people (those not like me) for the purpose of treatment or differential allocation of resources. Such self-categorization occurs in (1) nations that compete for human and natural resources, (2) corporations that compete for customers and sales, and (3) other groups that are physically distinguishable and that compete for services and opportunities within the same society. This conflict between groups has no simple cause, and no totally effective solution. Nevertheless, Muzafer Sherif (1958) did demonstrate that it is possible to achieve harmony between opposing social groups, by introducing what he called “superordinate goals.” These are goals for both groups that can be achieved only through the cooperation of both.

In Sherif’s “Robbers Cave” experiment (so named for its site, Robbers Cave State Park in Oklahoma), boys attending a summer camp were, in the first phase of the study, divided into two groups that functioned independently of each other. In the second phase, the groups opposed each other, participating in competitive and frustrating activities in which only the winning group could have valued resources. The experiment demonstrated that (1) members developed unfavorable attitudes and deroga-

**BIBLIOGRAPHY**

*Sheng-mei Ma*
tory stereotypes of the out-group, (2) social distance developed to the point of mutual avoidance, and (3) hostile attacks sometimes occurred. In the final phase of the experiment, the technique—superordinate goals—proved effective in reducing tension between groups by introducing goals that were shared by members of both groups and required collaborative efforts.

Several recent studies have identified aspects of Sherif’s technique that contribute to the effectiveness of superordinate goals in reducing conflict. One of the most critical aspects is the ability of superordinate goals to create a sense of shared identity. John Dovidio and colleagues (2001) intervened in the functioning of two groups to change people’s conceptions of their membership from that of diverse membership (in different groups) to common membership in a single, more inclusive group. The study revealed that if members of different groups are induced to conceive of themselves more as a single, superordinate group rather than as two separate groups, attitudes toward former out-group members will become more positive. Thus, cooperative relationships between groups, such as those established in Sherif’s Robbers Cave study, can reduce bias not only by ameliorating realistic group threat, but also by establishing a more inclusive, superordinate group identity (Gaertner et al. 2000).

There is little doubt among scholars regarding the ultimate benefits of the pursuit of superordinate goals rather than goals peculiar to nationalistic or individualistic interests. Superordinate goals enable people from opposing sides to come together and work toward a common end. In the everyday work environment, for example, the alignment of employer and employee goals with regard to job security can minimize conflict (Worchel and Simpson 1993). Within corporations there are superordinate goals that emphasize, in the words of AT&T’s slogan, “being the best.” The adoption of such a common goal has served to boost morale as well as minimize labor-management conflict. Superordinate goals also can be introduced to minimize group conflict at the level of large social groupings; at the global level these include activities such as space exploration, medical research, pollution control, and nuclear disarmament (Frank 1983).

SUPPLY

In economic theory, supply is the relationship between the price of a product and the number of units of product that producers are willing to offer for sale per unit time (called quantity supplied) when all other relevant factors, excluding the price of the product, remain fixed. The concept of supply ignores the effect of consumers on the market by assuming that consumers purchase as many units as producers offer for sale. The assumption that other factors remain fixed is known as the ceteris paribus assumption. For example, suppose that when the price of a product is $10 per unit, producers are willing to offer one million units of product for sale each month (the quantity supplied). Holding all other things constant, if the price of the product were to rise to $12, producers would make more profit on each unit and so producers would be enticed to offer more units for sale—the quantity of units supplied would rise. Similarly, holding all other things constant, if the price of the product were to fall to $8, producers would make less profit on each unit and so producers would be enticed to offer fewer units for sale—the quantity supplied would fall. Supply is this positive relationship between price and quantity supplied. Plotting various prices against the corresponding quantities supplied yields a graph called the supply curve. The supply curve is a pictorial representation of supply.

A shift in supply (also called a change in supply, or a supply shock) occurs when the number of units producers are willing to offer for sale changes for a reason unrelated to the price of the product. A shift in supply represents a new relationship between price and quantity. For example, suppose producers are willing to offer one million
units of product for sale each month when the price per unit is $10. An increase in the costs of labor and materials reduces the producers’ profit margins and so reduces the producers’ incentives to produce. As a result, even if the price of the product were to remain fixed at $10, producers would no longer be willing to offer one million units of product for sale each month. Alternatively, suppose that a change in technology enables producers to produce at a fraction of the cost at which they used to produce. The new technology increases the producers’ profit margins and so increases the producers’ incentives to produce. As a result, even if the price of the product were to remain fixed at $10, producers would be willing to offer more than one million units for each month.

Most supply shocks (or violations of the ceteris paribus assumptions for supply) can be categorized as:

- changes in the prices of factors;
- changes in the technology the firm employs; and
- changes in the number of firms in the industry.

Factors are things the firm uses in producing its product. Examples of factors are labor, materials, energy, buildings, machinery, and land, the last three of which are a special type of factor called capital. Capital factors are factors that are used in the production of the product but that are not used up in the production (except in the sense of depreciating). Noncapital factors (labor, materials, energy) are used up in the production. For example, a firm uses steel and robots to produce cars. The steel that is used to produce one car cannot be used to produce a second car because the steel was used up in the production of the first car. The robot, however, can be used to produce one car and then used to produce a second car. The robot is not used up when the first car is produced. Therefore, the robot is a capital factor and the steel is a noncapital factor.

When the price of a factor declines, it becomes more profitable for producers to produce, so quantity supplied increases even if the price of the product remains constant. This is an increase in supply. Similarly, when the price of a factor increases, it becomes less profitable for producers to produce, so quantity supplied decreases even if the price of the product remains constant. This is a decrease in supply.

Technology is an intangible that represents the sophistication of the production process. For example, one hundred workers can produce one car every six months when each worker works on his own car. But, when the workers are arranged in an assembly line with each worker performing a specialized task, the one hundred workers can produce one car every day. The rearrangement of the workers into an assembly line is an improvement in technology. Prior to the invention of the Bessemer process, it was so difficult to refine aluminum that aluminum was more expensive than gold. In the 1800s Henry Bessemer discovered that injecting oxygen into the aluminum while it was melted allowed far more aluminum to be refined for the same cost. This discovery was an improvement in technology.

When technology improves, it becomes more profitable for producers to produce and so quantity supplied increases even if the price of the product remains constant. This is an increase in supply. If technology were to devolve, it would become less profitable for producers to produce, so quantity supplied would decrease even if the price of the product remained constant. This would be a decrease in supply.

The number of firms in the industry typically changes as the industry’s profitability changes. If the industry becomes more profitable than other industries of comparable risk, new firms will enter the industry, thereby increasing supply. If the industry becomes less profitable than other industries of comparable risk, existing firms will leave the industry, thereby decreasing supply.

When the number of firms in an industry declines, the quantity supplied decreases even if the price of the product remains constant. This is a decrease in supply. When the number of firms in an industry increases, the quantity supplied increases even if the price of the product remains constant. This is an increase in supply.

Supply (sometimes called industry supply) typically refers to the aggregate production of all firms in an industry. One can refer to the supply of a single firm (the individual supply, or firm’s supply). In a perfectly competitive environment, a single firm’s supply curve is the portion of the firm’s marginal cost curve that is above the firm’s average variable cost curve. That is, assuming that the price of the firm’s product is high enough so that it is more profitable for the firm to produce than to shut down (i.e., the price is greater than the firm’s average variable cost), the minimum price required to entice the firm to offer one more unit of product for sale is the cost to the firm of producing that additional unit (i.e., the marginal cost). Individual supply curves can be combined to form industry supply via the method of horizontal addition. At each price, the quantities supplied by the various firms are added to attain a single quantity supplied for the industry as a whole. When supply is represented graphically, the price is typically shown on the vertical axis and the quantity supplied is shown on the horizontal axis. Thus combining the quantities supplied of the various firms entails adding the quantities shown on the horizontal axis while holding the numbers on the vertical axis fixed. In the example below, when the price of the product is $10 per unit, Firm #1 offers 200 units and Firm #2 offers 100 units. If these are
the only two firms in the industry, then the industry as a whole offers 300 units when the price is $10.

The steeper the slope of the industry supply curve, the less responsive the quantity supplied to changes in the price of the product. In the extreme case of a vertical supply curve, the quantity supplied remains fixed regardless of how high or low the price of the product might go. For example, the supply of seats at a stadium is vertical. Regardless of how high the price of tickets might go, the number of seats cannot change (at least not in the short run).

The concept of supply, and its linkage via demand to equilibria, was first formalized by the British economist Alfred Marshall (1842–1924) in his 1890 book *Principles of Economics*. Marshall was one of the first to conceptualize the behavior of producers and consumers independently. The approach, though common today, was not intuitively obvious. The data economists observed was equilibrium data—prices and quantities that arise only after the forces of demand and supply interact. To conceive of supply as an independent force required intuiting the existence of forces that could not be observed directly, but only inferred theoretically. Today, modern econometric techniques allow economists to obtain statistical estimates of supply and demand, but such techniques, even had they existed in 1890, would have been virtually impossible to implement without computers.

In the same way supply ignores the effect of consumers, demand ignores the effect of producers. The result is two behavioral paradigms: Supply summarizes the behavior of producers who exist (relative to consumers) in a vacuum; demand summarizes the behavior of consumers who exist (relative to producers) in a vacuum. Economists then combine demand and supply together to predict what price and quantity will result when consumers and producers are allowed to interact. The resultant price and quantity is called the equilibrium.

SUPREME BEING

Supreme being is a seventeenth-century descriptor for God. Given that the social sciences are a modern phenomenon, this designation is appropriate. In an attempt to accommodate the growing awareness of the pluralism of beliefs in the world, supreme being became a generic term for the entity that underpins the various world faiths.

CONCEPT OF THE SUPREME BEING

The concept of a supreme being starts with a sense that “something” must be responsible for this world around us. The idea of a creator is key, for this creator requires worship (i.e., an acknowledgement of human dependence on and love for the creator). It is this combination of creator and worship that drives most religious traditions to monotheism. Even in Hinduism, there is an emphasis on the underlying unity of the many in the one.

For the sake of simplicity, theistic traditions talk about an omnipotent, omniscient, and perfectly good God. Unlike a limited God (where the issue of the limits of God’s power or knowledge could be endlessly debated), theism invites us to affirm an unlimited God, where each attribute is stretched out to infinity.

A crucial area of discussion involves the relationship of the supreme being to time. In Judaism, Moses Maimonides (1135–1204), for example, addressed the issue; in Islam, Ibn Sina (980–1037); and in Christianity, Thomas Aquinas (c. 1225–1274). There is agreement that God is outside time—so there is no duration in the life of God (see Burrell 1986). In addition, God has timeless knowledge of the future—God knows the beginning to the end. However, in the modern period, we find in all three traditions a growing sympathy with the view that God is everlasting (i.e., time is part of God, but there was never a time when God was not and will never be a time when God ceases to be).

Under the influence of Alfred North Whitehead (1861–1947), a movement known as process theology emerged that suggests that God’s omniscience does not include the decisions of free-will creatures because, by definition, genuinely free decisions are not known until they are made (see Whitehead [1929] 1960). The concept of the supreme being that emerges from this account is often pantheist (God and the world are identified together) or panentheist (God and the world are identified together, but God is more than the world). This view has more in common with Hindu traditions than with classical Christianity.

ARGUMENTS FOR A SUPREME BEING

For those traditions heavily influenced by Hellenistic thought (i.e., Greek learning), certain arguments emerged to defend the rationality of belief in God. In the Islamic, Jewish, and Christian traditions, two arguments came to the fore. The first is the design argument. With its roots in the Timaeus of Plato (427–347 BCE), it flourished in the writings of Aquinas and William Paley (1743–1805). The argument seeks to draw a parallel between a human artifact (for Paley it was a “watch”) and the world. A watch is clearly intended for and serves certain purposes (even if you do not know what a watch is for, its purpose could be deduced). The cosmos, with all its complexity, is the same. From a watch, we can infer a watchmaker; so from the cosmos, we can infer a designer.

Contemporary defenders of the design argument abound. The Muslim thinker Bediuzzaman Said Nursi (c. 1877–1960) constructs the argument in The Words (1928). For many Western philosophers, it is widely believed that David Hume (1711–1776), in Dialogues Concerning Natural Religion (1779), effectively undermined the design argument. Hume’s first problem is the analogy: Is the world really like a human artifact? The whole argument depends on this analogy: If one likens the world to a giant vegetable, then the human mind does not automatically leap to design and order. Instead, we shall find ourselves thinking of gradual growth—an image that does not require a creator. Hume’s second problem is that the argument does not get back to God. At best, explains Hume, the argument takes us back to a designer, but we have no reason to assume that this designer is omnipotent, omniscient, or perfectly good. Indeed, given evil and suffering in creation, we have good reason to assume that the designer is not omnipotent or perfectly good. Hume’s third problem is that there are naturalistic explanations for the world’s order. Hume was living before Charles Darwin (1809–1882) formulated the natural selection hypothesis. However, other writers have explored the ways in which Darwin undermines the design argument. Richard Dawkins (2006), a biologist at Oxford University, argues that the order in the world is due to the fact that those things that do not fit in do not survive. The world’s order is not due to a creator organizing everything in advance.

The cosmological argument takes a variety of forms. Among the best known is the Islamic Kalām argument for a first cause to the universe. The presumption is that one cannot have an infinite regress of causes. So the universe must have an immaterial first cause that is responsible for everything that follows. Scholars have contested the pre-
sumption that there cannot be an infinite regress of causes; after all, no one complains that $\frac{22}{7}$ (pi) must finish somewhere before it can be considered intelligible. In addition, Stephen Hawking (1988) has suggested that the combination of cosmology and quantum mechanics might create the conditions for a universe to just start.

Given all this, there is more interest in the argument of Thomas Aquinas. In the *Summa Theologica*, Aquinas explains that he believes that the universe has a start only because of the Genesis story; his instinct is to follow his Greek masters and affirm that matter is eternal. However, he still accepts that rationally it is necessary to posit the existence of God to explain "why anything is" and "how it continues to be." The third of his "five ways" (arguments) to God's existence insists that the intelligibility of the universe depends on a necessary being. If everything is contingent (could be otherwise), then ultimately it would remain unexplained (because we would still have questions about the "why" and the "how"). So, for the universe to make sense, it depends on a necessary being (a being who contains within itself the reason for its own existence). Debate around this form of the argument hinges on the coherence of the idea of a necessary being. Recent defenders of this argument have linked it with the nature of truth (see Markham 1998).

Brief mention should be made of the *ontological argument*. Formulated by Saint Anselm (1033–1109) and then popularized by René Descartes (1596–1650), the ontological argument is an exploration of the meaning of the word *god*. Anselm points out that even the atheist understands the concept of God (otherwise atheists would not know what they were denying). Given that the concept of God includes perfection—the greatest conceivable being—(or in Anselm's terminology, "that than which nothing greater can be thought"), it follows that an imaginary God would not be the greatest conceivable being because the greatest conceivable being would be one that exists both in the mind and reality. Therefore, if the idea of the greatest conceivable being makes sense, then such a being must exist. This argument continues to provoke considerable debate. Recent defenders include Alvin Plantinga (1965).

There are several other arguments for belief in a supreme being. Immanuel Kant (1724–1804) in his *Critique of Practical Reason* (1788) insists that the existence of a supreme being is a necessary postulate of moral discourse. C. S. Lewis (1898–1963) argued that moral discourse does not make sense unless it is grounded in a transcendent being, which is the locus of such values. More recently, some have suggested that there is a pointer to the transcendent in music, beauty, or art (see Steiner 1989).

One major objection to belief in a supreme being is the problem of evil. The traditional form of the problem is a logical one: If God is all powerful, then God must be able to abolish evil; if God is all loving, then God must wish to abolish evil. Yet evil exists, so God cannot be all powerful and all loving. This problem has generated a vast literature on *theodicy* (an attempt to justify God in the light of evil) (see Hick 1977). For some, the social sciences have undermined religion by providing a naturalistic explanation for the religious phenomenon.

**BELIEF IN A SUPREME BEING**

It is not clear how influential these arguments are on belief in a supreme being. Belief in God is a result of a web of practices that take an elaborate social form. Despite secular expectations to the contrary, belief in a supreme being is widespread. As children learn a language, so, running parallel, a religious worldview is formed. For many people, the concept of the supreme being is nebulous, and there is little clarity about the arguments for a supreme being's existence. Yet there are rich resources in the different world faiths; these can provide both a coherent account and some strong arguments for the supreme being.

SUPREME COURT, U.S.

Article III of the U.S. Constitution states that “[t]he judicial Power of the United States, shall be vested in one supreme Court, and in such inferior Courts as the Congress may from time to time ordain and establish.” While the Constitution establishes a Supreme Court, it does little to describe what the Court will look like or what it will do. Nevertheless, the Supreme Court has developed over time to become a key player in the U.S. policy process.

COMPOSITION AND FUNCTION OF THE COURT

With respect to composition, the Constitution provides that the justices of the U.S. Supreme Court will be appointed by the president, with the advice and consent of the Senate, and absent some malfeasance in office (which might result in their impeachment), they enjoy life tenure. As a result, appointing Supreme Court justices provides presidents with an opportunity to leave an enduring policy legacy; William Rehnquist was appointed by Republican president Richard Nixon in 1972, yet he remained a strong conservative force on the Court until his death in 2005.

The number of members of the Supreme Court is determined by statute rather than spelled out in the Constitution. During the first century of the Court’s history, the number of justices varied from five to ten. In 1869, the number was set at nine, and it has held constant ever since.

Of the nine members, eight are associate justices and one serves as the chief justice. The position of chief justice must be filled specifically by the president. Thus, when Chief Justice Warren Burger retired in 1986, President Ronald Reagan nominated William Rehnquist—who was already serving as an associate justice—to the position of chief justice; although the Senate had confirmed Rehnquist as an associate justice in 1972, they had to confirm him as chief justice again in 1986.

People sometimes refer to the chief justice as “first among equals.” The chief justice’s vote does not count more than that of any other justice. However, regardless of his actual time served on the Court, he automatically has more seniority than any associate justice. As a result, he speaks first at conferences—meetings to discuss the merits of cases—and, if the chief justice is in the majority, he determines who will write the Court’s opinion. The position of chief justice also entails some additional administrative and ceremonial responsibilities.

With respect to function, the Constitution provides that the Supreme Court has original jurisdiction—the ability to hear the case first, before any other court—over disputes between states, disputes between states and the federal government, and cases involving foreign diplomats. In all other cases, the Supreme Court exercises appellate jurisdiction; that is, it can only review the decision of another court. Because fact-finding is generally relegated to trial courts—courts with original jurisdiction—the Supreme Court is generally limited to resolving disputes over the meaning and application of the law.

Among the cases over which the Supreme Court exercises appellate jurisdiction, the overwhelming majority are brought to the Court through a petition for a writ of certiorari. The Court has complete discretion over whether to grant the petition and hear the case or not. Indeed, the Supreme Court grants relatively few of the petitions filed with it. During the Court’s 2002 term, 8,225 cases (including appeals, original jurisdiction cases, and extraordinary writs) were brought before the Supreme Court, yet the Court granted full review to fewer than 100.

A significant body of scholarship is devoted to determining how and why the Court chooses which cases it will hear. Empirical evidence suggests that the Court chooses to hear cases that give it the greatest opportunity to make policy: cases that present significant legal issues that will have broad impact on the legal landscape and, in particular, cases the court below decided “wrongly.” In other words, as long as the state and lower federal courts are deciding legal issues in a way that is consistent with the policy and legal preferences of the Supreme Court justices, the justices will generally let those lower court decisions stand. The Court is far more likely to accept a case to correct a perceived error on the part of the lower courts.

JUDICIAL REVIEW AND U.S. POLICY

While determining who wins and who loses legal disputes is arguably an inherently political activity, the U.S. Supreme Court plays its most active role in the American political process when it exercises judicial review. Judicial review is the power to evaluate whether state and federal government actions, both legislative and executive, comport with the Constitution and, if they do not, declare those actions void.

The U.S. Supreme Court first exercised judicial review in the 1803 case of Marbury v. Madison. In February 1801, outgoing president John Adams signed a number of judicial commissions, but his secretary of state, John Marshall, did not deliver them before the end of Adams’s term. When the new president, Thomas Jefferson, took office, his secretary of state, James Madison, refused to deliver the commissions. William Marbury, one of the individuals who did not receive his commission, brought a claim directly to the U.S. Supreme Court. Interestingly, by this point, John Marshall had taken office as the chief justice of the Supreme Court.
Marbury brought his claim directly to the Supreme Court because a provision of the Judiciary Act of 1789 gave the Supreme Court the power of original jurisdiction over such matters. When the Supreme Court finally issued its decision in 1803, Chief Justice John Marshall concluded that the Court could not compel the president to deliver the commission to Marbury because Congress could not expand the Supreme Court’s original jurisdiction beyond that described in the Constitution. The Court was unable to help Marbury, but it achieved its result by declaring an act of Congress unconstitutional and void.

The _Marbury_ decision was relatively uncontroversial when it was issued. Chief Justice Marshall made it clear that the Court’s role in exercising judicial review was limited to making legal, rather than political, determinations. In its earliest incarnation, judicial review was considered an almost ministerial function that gave the Court relatively little policymaking prerogative. As time passed, however, the potential for policymaking through the exercise of judicial review became clear.

In the late 1920s and early 1930s, the full power of judicial review was revealed. Specifically, as Congress began to pass social legislation in response to the Progressive movement and as President Franklin Roosevelt began to implement his New Deal economic policies, the Supreme Court stood squarely in the way of elected-branch policymaking. The Court issued a number of decisions striking down social and economic legislation on the grounds that it violated constitutional notions of federalism and individual liberty.

In 1937, following a string of Supreme Court decisions striking down New Deal programs, Roosevelt proposed a plan to “pack” the Court: On the pretext of assisting an overworked and elderly Supreme Court, Roosevelt proposed creating a new seat on the Supreme Court for every justice who was seventy years old or older and who remained on the Court. The result would have been to add six new seats, and those seats would, of course, be filled by judges friendly to Roosevelt’s New Deal programs.

Within weeks of Roosevelt’s proposal, Justice Owens Roberts abandoned the Court’s anti–New Deal faction to create a narrow majority that supported the constitutionality of Roosevelt’s programs. Roberts’s apparent aboutface is often referred to as the “switch in time that saved nine” because his change in position helped preserve the nine-member Supreme Court. Historical examination of the Court’s deliberations from this time period indicate that Roberts had cast his pro–New Deal votes on the cases in question weeks before Roosevelt announced his plan; in other words, the coincidence between the threat to pack the Court and Roberts’s change of position was just that—a coincidence.

Still, the Court’s ability to stall implementation of significant social and economic programs highlights the potential of judicial review as a political force. Moreover, the shift in Supreme Court policy during the 1930s emphasizes the amount of discretion that the Court has in interpreting the Constitution. Although Chief Justice Marshall described judicial review as a mechanical application of clear legal principles, the events surrounding the New Deal demonstrate the extent to which the Constitution is subject to a wide range of interpretation. Indeed, since the 1930s, there has been an increasing awareness of the political implications of Supreme Court membership, and the nomination and confirmation process has become quite politically charged.

Any lingering doubt about the political dimension of the Court’s exercise of judicial review was dispelled during the tenure of Chief Justice Earl Warren. Warren was appointed by a conservative president—Dwight Eisenhower—but his time on the Court was marked by a clear liberal agenda. Warren was particularly interested in expanding the rights of criminal defendants, and his time on the Court is marked by numerous decisions that broadly construe the individual rights the Constitution guarantees to criminal defendants.

Among the cases that make up Chief Justice Warren’s legacy are _Miranda v. Arizona_ (1966) and _Gideon v. Wainwright_ (1963). In _Miranda_, the Supreme Court held that the Fifth Amendment protection against self-incrimination requires police to inform any criminal suspect in their custody of their constitutional rights; specifically, _Miranda_ requires the police to inform suspects in custody that they have the right to remain silent and decline to answer any questions. The _Miranda_ decision is particularly striking because it delves into the nuts and bolts of police procedure, setting fairly “bright line” requirements for the policy to follow.

In _Gideon v. Wainwright_ (1963), the Supreme Court ruled that the Sixth Amendment guarantee of effective assistance of counsel requires states to provide attorneys to indigent criminal defendants. In other words, the state must pay attorneys to represent criminal defendants who are too poor to hire attorneys on their own. Implementation of the _Gideon_ decision has imposed considerable financial burdens on the states.

Both the _Gideon_ and _Miranda_ decisions reflect Chief Justice Warren’s personal ideological agenda. First, both decisions give higher priority to the rights of the individual than to the rights of the state; procedural and financial burdens placed on government take second chair to the rights guaranteed individuals by the Constitution. Second, both decisions reflect Warren’s belief that the U.S. Supreme Court plays a countermajoritarian role in U.S. politics. While the legislative and executive branches
respond to the will of the majority, Warren (and many others) viewed the courts as providing a voice and a forum to those who are socially marginalized, such as the poor.

THE SUPREME COURT AND CONSTITUTIONAL DIALOGUE

Two politically charged issues—race and abortion—highlight both the political aspect of judicial review and the role of the Supreme Court in a broader political dialogue. In both issue areas, the Supreme Court has played a key role in setting U.S. policy. Yet in both issues, the constraints placed on the Court and the dialogue between the Court and other political actors is apparent.

In 1857, the Supreme Court issued a decision in the case of Scott v. Sandford (better known as the "Dred Scott decision"). Legally, Dred Scott was a significant statement about the importance of states' rights. Politically, however, Dred Scott was important because the Court held, essentially, that even emancipated slaves could not be full citizens of the United States. In an already tumultuous political climate, the Dred Scott decision became a rallying point for abolitionists and contributed to the outbreak of the U.S. Civil War and, ultimately, to the enactment of the Fourteenth Amendment’s guarantee of equal protection of the laws.

In Plessy v. Ferguson (1896), the Court considered a Louisiana statute that required separation of the races on all railroads. In finding that the Louisiana statute did not violate the Fourteenth Amendment, the Court explicitly rejected Plessy's argument that segregation marginalized African Americans and perpetuated the belief that African Americans were inferior. Yet in Brown v. Board of Education of Topeka (1954), the Court outlawed segregated schools precisely because of the social stigma associated with segregation. What changed? The political climate had changed dramatically; between 1896 and 1954, African Americans had gained considerable electoral strength. Moreover, the composition of the Court had changed. Specifically, the Brown decision was vetted by a newly appointed Chief Justice Earl Warren.

The change in jurisprudence between Plessy and Brown illustrates both the importance of the ideology of individual members of the Court and the importance of a favorable political climate for the Court’s exercise of power. The Court's decision in Brown could be implemented only with the support of the president, who mobilized the National Guard to force southern states to integrate their public schools.

The issue of race provides further illustration of the interplay between the Court and the elected branches. The Supreme Court has struggled to articulate a clear, concise position on the issue of affirmative action, leaving states to formulate their policies through a process of trial and error. In 1978, the Court first addressed the issue of affirmative action in higher education with the case of Regents of the University of California v. Bakke. In Bakke, the Court indicated that some affirmative action programs might be constitutionally acceptable, but the University of California program was not. Over the next twenty-five years, public universities across the country attempted to develop constitutionally acceptable yet effective affirmative action policies, but the Court failed to provide clear guidance. In 2003, the Court issued two decisions on the issue of affirmative action, and universities hoped that the issue would finally be resolved. In Gratz v. Bollinger, the Court struck down the University of Michigan’s affirmative action program for undergraduate admissions; in Grutter v. Bollinger, the Court upheld the affirmative action program for the University of Michigan’s law school. Taken together, the two decisions indicate that diversity in education is a compelling government interest, that public schools can consider racial diversity in admissions decisions, but that race cannot be given any precise, explicit weight in the decision process. The decisions provide guidance, but they are far from defining exactly when and how public universities may consider race in admissions.

While the issue of race illustrates the interplay and interdependence of the courts and elected government over the course of more than a century, the issue of abortion provides a more succinct yet equally compelling illustration. In 1973, following the relaxation of numerous state anti-abortion laws, the Supreme Court issued its landmark decision in Roe v. Wade. In Roe, the Court held that the right to privacy—which is not enumerated in the Constitution but which the Court had previously inferred from a number of constitutional provisions—protected the right of a woman to obtain an abortion. In a remarkably "legislative" opinion, the Court expounded that a woman's right to privacy completely dominated the state's interests during the first trimester of pregnancy but the two obtained more equal footing as the pregnancy progressed.

The Roe decision ignited a firestorm of controversy. It mobilized anti-abortion activists and helped solidify a full-fledged anti-abortion movement in American politics. It prompted conservative state governments to enact increasingly restrictive anti-abortion legislation in an effort to test the boundaries of Roe and lead to the Court overturning its decision. It made the issue of abortion and the right to privacy a sort of litmus test in judicial nominations and confirmations. In the wake of Roe, the effect of the Court on politics and that of politics on the Court are stark.

**SURPLUS**

In the history of economic thought there are, broadly, two approaches to the study of prices and income distribution. The neoclassical, or marginalist, approach is the dominant modern theory. But there is an older approach rooted in the writings of William Petty and François Quesnay (in his *Tableau Économique*) and in those of authors in the classical school of political economy such as David Ricardo and Karl Marx. Classical economists considered the surplus to be that portion of the annual social product left over after deducting one part to replace the means of production used up and another part to pay workers for their consumption. The classical economists generally took the view that wealth creation is the productive combination of direct human labor and means of production, where the latter was considered to be indirect labor because it was the result of previous periods’ labors.

While the centrality of labor in the production process was a theme that was common to the writings of most classical economists (Hunt 2002, chapter 2) it was in the writings of Marx that the labor theory of value (LTV) reached its fullest level of development. The LTV states that the value of a commodity is equal to the total amount of direct and indirect labor time (or labor value) that is necessary for its production, given demand and technology. Further, in the Marxian perspective money prices are assumed to be regulated by labor values. It is quite simple to understand this, for if in the production of a good the direct labor productivity rises and/or the labor productivities in the industries that supply its inputs rise, then its unit labor value will fall. Consequently, given wage rates, its unit costs will also fall, thereby allowing firms to lower their unit selling prices.

Let $c =$ labor time needed to produce the means of production used up daily and $l =$ the direct labor time per day needed to produce a given amount of output. If money prices are proportional to the total labor time, as assumed by Marx (*Capital Volume I*), then unit money price will be proportional to $c + l$. Let $v =$ labor time needed to produce wage-goods so that money wages are proportional to $v$. Then unit money cost of production will be proportional to $c + v$. Thus unit money profits or surplus value will arise if and only if $c + l > c + v$, that is to say, $l > v$. Hence collectively workers need to work for a length of time that exceeds the time needed to produce wage goods (Shaikh 1987).

**MODERN DEBATES**

Nonetheless, not all contemporary authors who subscribe to the surplus approach consider the LTV to be valid. These authors base their position on Piero Sraffa’s (1960) reevaluation of the Ricardoan LTV. Ricardo’s struggles with the LTV can be understood by remembering that the general rate of profit equals the aggregate surplus divided by the aggregate capital advanced. However, in a world of heterogeneous commodities the numerator cannot be divided by the denominator in this equation unless they are rendered commensurate in value terms. That is, one needs to know their prices beforehand. However, prices themselves are affected by changes in income distribution between wage and profit rates, thereby introducing an element of circular reasoning into the theory. This was the basis of Ricardo’s attempts to search for an invariant measure of value that would be immune to the changes in the distribution of income.

Contemporary Sraffian authors reject the relevance of labor values and take the position that physical production data and cost structures are sufficient to simultaneously determine relative prices and profit rates (Kurz 2006, p. 9). Authors in this school consider the LTV to be redundant because of the apparent autonomous movements of prices and profits (Steedman 1977). On the other hand, Shaikh (1982, 1984) argues that this autonomy is an illusion, as random fluctuations of market prices around values will bring about transfers of surplus value between different sectors that will result in only limited deviations of actual profits from surplus value.

To understand Shaikh’s argument it is necessary to draw on Marx’s distinction between the circuit of indus-
trial capital and the capitalist circuit of revenue. In the former variable capital is advanced to hire workers who are combined with raw materials and machinery (or constant capital) to produce an output. In the latter circuit capitalist households use all or part of the surplus value produced in the first circuit to purchase a portion of the output. One may further subdivide the circuit of capital into three departments that respectively produce raw materials and machinery (Department I), workers’ consumption goods (Department IIA), and capitalist households’ consumption goods (Department IIB).

Let prices be initially equal to values in all three departments. Then a decrease only in the aggregate price of the output of Department I will lower input costs in all departments, as constant capital is a common input. A price decrease in only Department IIA output will have the same effect because, given real wages, lower prices of Department IIA output will also lower advances for variable capital, another common input, in all three sectors.

The drop of price below value in Department I will squeeze profits only in that department and will create excess profits in the other two departments. The same will hold true for a price decrease only in Department IIB. Then in both situations the price-value deviation will be accompanied by a transfer of value within the circuit of capital from one department to another.

In contrast, a fall in the price of only department IIB output will leave all sectors’ production costs unaffected but will entail a revenue gain on capitalists’ personal accounts, as the money-value that they pay to purchase goods will be lower than the value of these goods. In other words, there will be a transfer of surplus value from the circuit of capital to the capitalist circuit of revenue, producing a fall of aggregate profits in the latter. However, if such transfers between the two circuits are ignored then an illusion is created that profits vary independently of surplus value (Marx 1971, p. 347).

**IMPLICATIONS**

It should now be clear that the extent of profits–surplus value deviations will depend on price-value deviations in Department IIB and on surplus value transfers between the two circuits. If all surplus value is consumed as revenue by capitalists the profit–surplus value deviation will be a maximum; conversely if all surplus value is reinvested there is no circuit of revenue and the profit–surplus value deviation will be zero.

More generally, an important implication of this framework is that the balance between production and non-production activities determines an economy’s growth rate. Production activities are those that create surplus value while non-production activities are ones that subsequently utilize it or use it up in some way (Shaikh and Tonak 1994, chapter 2). This distinction between these two types of activities has some implications for the role of the State if the aim is to raise the growth rate. First, non-productive expenditures by the State should grow at a rate which is slower than the growth of production activity. Second, there could be a policy of increasing the proportion of production activity (e.g., generation of electricity) by the State. Finally, along the lines discussed by Nicholas Kaldor (Palma and Marcel 1989), taxation policies could be implemented to squeeze (luxury) consumption spending by capitalist households and encourage the retention of a greater proportion of surplus value within the circuit of capital.

SURPLUS POPULATION
For classical political economists, the poverty and unemployment generated in the early stages of capitalist development denoted the existence of a surplus population caused by the inability of the poor to postpone marriage and behave in a rational and virtuous manner.

MALTHUS
The most influential exponent of this view was T. R. Malthus (1766–1834), author of the “population principle,” or “the constant tendency in all animated life to increase beyond the nourishment prepared for it” (Malthus [1798] 1933, p. 5)—widely invoked to legitimate poverty and inequality on the grounds of “natural laws.” According to Malthus, the principle’s “natural and necessary effects [are] … a very considerable portion of that vice and misery, and of that unequable distribution of the bounties of nature which it has been the unceasing object of the enlightened philanthropists in all ages to correct” (p. 5). Malthus based his principle of population on a “natural law,” the tendency of all forms of life, including human life, to increase beyond the available means of subsistence: When unchecked, he argued, population increases geometrically, doubling every twenty-five years, whereas food can increase only arithmetically (p. 8). That technological change and growth in the productivity of labor in agriculture and other areas of economic activity have proven Malthus wrong have not undermined, however, the continuing ideological value of his principle as a tool for legitimating poverty, inequality, underdevelopment, war, and human misery in all its forms. For example, Robert Kaplan (1994), writing about the conditions in West Africa in the mid-1990s—which, in his view, portended a twenty-first century engulfed in anarchy, disease, and overpopulation—states: “It is Thomas Malthus, the philosopher of demographic doomsday, who is now the prophet of West Africa’s future. And West Africa’s future, eventually, will be that of most of the world” (p. 48).

MARX
Marx’s alternative to Malthus’s principle of population is the principle of the reserve army or relative surplus population, which captures the effects of changing patterns of capital accumulation upon the working population (Marx [1867] 1967, chapter 25). Theoretically, the process of capital accumulation entails increases in the demand for labor, which, in turn, lead to increases in the value of labor power; that is, as the supply of labor declines, capitalists are compelled to offer higher wages to entice workers to their enterprises. The effect of higher wages is a reduction in profits. In practice, wages tend to rise together with capital accumulation, but they never rise enough to endanger the system itself. For the classical political economists and for Malthus, in particular, the mechanism that kept wages equal to their “natural” price (that is, equal to the minimum level of subsistence) is embodied in the principle of population. When wages rise, workers overproduce themselves, and this increase in the size of the population produces a supply of labor greater than the demand, so wages fall to their “natural” price, that is, to a minimum level of subsistence. Under these conditions, workers could improve their situation only by controlling their numbers, thereby raising the price of labor. Poverty and unemployment are, therefore, the result only of workers “natural propensity” to reproduce beyond the available means of subsistence.

Against Malthus, Marx observes that capital accumulation does not automatically entail increases in the demand for labor because as the forces of production develop, the organic composition of capital changes. From the perspective of its value composition, capital is composed of constant capital (the value of the means of production) and variable capital (the value of labor power). From the perspective of its technical composition, capital is composed of the means of production and living labor. Changes in the technical composition produce changes in the value composition, and this correlation between the two is the organic composition of capital (Marx [1867] 1967, p. 612). In the process of capital accumulation, the organic composition of the total social capital changes; the constant increases at the expense of the variable component, and “since the demand for labor is determined not by the amount of capital as a whole but by its variable constituent alone, that demand falls progressively with the increase of total capital…. It falls relatively to the magnitude of the total social capital and at an accelerated rate” (p. 629). The logic of capital accumulation inexorably produces unemployment, the constant presence of a “relative surplus population” or “reserve army of labor” whose size and composition will vary with the specific needs of capital accumulation in a given social formation. It follows that the relationship between the level of employment and the size of the population is not determined by the latter but by the organic composition of capital invested at a given time: “the more or less favorable circumstances in which the wage-working class supports and
Surplus Population

multiplies itself, in no way alter the fundamental character of capitalist production” (p. 615). Capital accumulation, therefore, is indifferent to and independent from rates of population growth (pp. 640–641).

SURPLUS POPULATION IN THE TWENTIETH AND TWENTY-FIRST CENTURIES

In the two centuries after the publication of Malthus’s work, the capitalist mode of production has penetrated even more deeply in all social formations. World capitalist accumulation has internationalized the reserve army of labor. Within advanced capitalist social formations, such as that of the United States, changes in the organic composition of capital resulted in automation, downsizing, outsourcing, deindustrialization, decline in the demand for skilled blue-collar labor, growth in the service and information-technology sectors of the economy, and increases in the demand for technical, professional, and managerial labor. As it could not be otherwise, such qualitative shifts in capital investment necessarily contributed to the existence and reproduction, through time, of a surplus population of fluctuating size and composition.

Changes in the organic composition of capital, however, are not the only cause of surplus populations. Welfare-state policies, the product of successful class struggles (especially in western Europe) and of the capitalist classes’ effort (especially in the United States) to avert social unrest and even revolution in the aftermath of the Great Depression, had unintended demographic consequences. By providing social services and minimal income payments to the unemployed, disabled, and poor, such policies contributed to the growth, through natural increase, of a large and relatively stable population of poor and near-poor people, unemployed and largely unemployable. Therefore, the surplus population in advanced capitalist societies is heterogeneous, including the recent and the long-term unemployed and a varying proportion of people who have never been employed and are likely to be unemployable. Illiteracy, lack of skills, age, responsibility for the care of small children or elderly relatives, criminal records, drug addictions, disability, mental illness, and so forth are some of the reasons millions of people have never or seldom entered the labor force. Also part of the surplus population are the homeless, prostitutes, and those who make a living through illegal activities, the “lumpenproletariat.” Finally, as the effects of globalization are felt more strongly among the more vulnerable sectors of the working classes, Latino immigrants—particularly the undocumented—have become the more visible and stigmatized sector of the surplus population. Even if most of them work in poorly paid manual jobs that most U.S. citizens refrain from doing, they are contradictorily perceived both as dangerous, unhealthy, idle, a burden for the taxpayers, and, at the same time, the cause of declining wages for low-skilled workers.

In racially heterogeneous societies such as the United States, blacks and other “nonwhite” populations have been deemed superfluous by the white elites or managerial classes (Darity 1983), a view reflecting the resilience and pervasiveness of racism across all social classes and the disproportionate presence of racial and ethnic minorities in the poverty population. And, given the economic and political interests of U.S. and European capitalist classes in the so-called developing world, their populations also were deemed superfluous, a drain on the world’s resources, the main cause of “underdevelopment,” political unrest, and revolutionary, anticapitalist and anticolonial struggles. Consequently, national and international strategies were devised to control the size of these surplus populations (Demerath 1976; Mass 1976; Gimenez 1977; Michaelson 1981; Bandarage 1997).

Within the United States, in the early twentieth century scientists lent support to eugenic theories of racial differences in intelligence and promoted immigration and sterilization policies designed to keep “inferior” (that is, non-“Nordic”) races from entering the country and to discourage the “unfit” (that is, the poor, Native Americans, blacks, Puerto Ricans, criminals, the mentally ill, alcoholics) from reproducing (DeFine 1997). While such government-sponsored policies are no longer in place, the practice of government-funded sterilization, made easily available to poor and nonwhite women, continues unabated; it has become the most widespread form of birth control among women older than twenty-five in the United States (Petchesky 1976) and, for all practical purposes, can be viewed as an effect of a “doctrine of preemptive extermination” aimed at the surplus population (Darity 1983). Presumably, sterilization is done with the women’s consent, but consent cannot be taken for granted when women are not fully informed of alternatives or when the alternatives—efficient use of contraceptives or abortion—are placed beyond their reach. Furthermore, the women who “choose” sterilization tend to be poor, Puerto Ricans, Latinas, African Americans, and Native Americans (Petchesky 1976; DeFine, 1997). The high incidence of sterilization constitutes a form of abuse and a strategy to control the growth of populations deemed superfluous because it is a form of birth control that, conservative rhetoric about the value of life notwithstanding, is made easily available and paid by federal and state funds. Abortion, on the other hand, though legal, is unavailable for most poor women, for the Hyde Amendment, passed in 1976, “excludes abortion from the comprehensive health care services provided to low-income people by the federal government through
Medicaid … Currently, only seventeen states fund abortions for low income women” (ACLU 2004).

Besides sterilization, poor women, especially women on welfare, are encouraged to use long-term forms of contraception, such as Depo-Provera, Norplant, or quinacrine (Chamberlain and Hardisty 2006) with problematic side-effects. These practices, supported by the political right, have affected the consciousness of people of color, women and men, who become suspicious of family planning programs and even perceive legalized abortion as part of a genocidal strategy against people of color. The political right exploits this perception, claiming to be “allies of these communities … pointing to ‘shared values’ on abortion and other social issues” (Chamberlain and Hardisty 2006).

Wishful thinking about the role of abortion in cutting down the size of the surplus population is epitomized in the notion that the legalization of abortion caused a decline in the crime rate: “In the early 1990s, just as the first cohort of children born after Roe v. Wade was hitting its late teen years—the years during which young men enter their criminal prime—the rate of crime began to fall. What this cohort was missing … were the children who stood the greatest chance of becoming criminals…. Legalized abortion led to less unwontedness; unwontedness leads to high crime; legalized abortion, therefore, led to less crime” (Levitt and Dubner 2005, p. 139). They assumed that, as safe abortions had been available to middle-class women before legalization, the women most likely to have had abortions after Roe v. Wade would be poor, in their teens, unmarried, or all three (p. 138) because now “any woman could easily obtain an abortion, often for less than $100” (p. 138). Their findings have been criticized and shown to be misleading because of statistical flaws; they ignored changes in the crime rate that would have undermined their arguments, and by focusing on the crime rates of 1985 and 1997 only, they ignored “the 800-pound gorilla of crime trends: the rise and fall of the crack epidemic during the intervening years … which first drove violent crime up in the late ’80s and early ’90s, then drove it down in the mid and late ’90s” (Sailer 1999). They should have been criticized also because they ignored the effects of the Hyde Amendment, which, after 1976, kept poor women—presumably those likely to give birth to potential criminals—in most states from having access to abortions. Regardless of the flaws in their research, their argument is ideologically powerful, strengthening racial stereotypes among whites and suspicion about abortion among nonwhites. What gets lost in the midst of these arguments is the need of all women, regardless of class, race, or ethnicity, to attain some control over their bodies. Women’s reproductive rights, their right to make free and informed decisions about childbearing, are endangered by the contradictions and ideological effects inherent in political discourses and practices that celebrate motherhood and urge white, middle-class women to reproduce and reject abortion while making abortion unavailable and pushing sterilization as the birth control of “choice” for poor, especially nonwhite, women.

Besides population control, prisons (many of them turned into workplaces) and the army are the other two strategies the dominant classes use to deal with the surplus population. The Malthusian spirit, captured in Scrooge’s reply to someone requesting a donation for the poor at Christmastime, is still alive: When told that many of the poor and destitute would rather die than go to the work house or prison, Scrooge said: “If they would rather die, … they had better do it, and decrease the surplus population” (Dickens [1843] 1876, p. 12).

SURPLUS VALUE

For Karl Marx, surplus value is critical to the expansion of capital. In the money circuit $M - C - M'$, capitalists purchase commodities ($C$) with money ($M$) in order to sell these commodities for more than their initial outlay ($M'$). Surplus value is the difference $M' - M$, the profit that the capitalist makes at the end of the money circuit. Instead of hoarding this profit, as would a miser, the capitalist reinvests it in a new, enhanced circuit of money. The conclusion of each circuit, with more value produced, provides the starting point for the expansion of capital in each subsequent circuit.

The problem that Marx (1867) sets himself in *Capital*, volume 1, is how capitalists can sell for more than they buy. Are some commodities sold for more than their cost? The answer is yes and no. Marx assumes that capitalists pay for the full cost of inputs such as raw materials, which are used in the production process. The yarn that is used by the weaver is paid for at full cost. However, there is one commodity that does beget more value than its cost: labor power.

On the one hand labor power, which is sold by workers to capitalists, has a capacity to produce output. The capitalist makes use of a worker’s labor power, say for eight hours per day, adding eight hours of value to the commodity produced. On the other hand it has a cost, which for the capitalist is the outlay of wages that enable workers, and their families, to subsist. Crucially, the value of this labor power is less than the value of the worker’s output. The worker may have to work only four hours per day to produce value that is equivalent to the goods required for subsistence. But, exercising control over the labor process, the capitalist requires an eight-hour day: the worker is robbed of four hours of labor power that is extracted by the capitalist as surplus value. For Marx, surplus value entails the exploitation of workers by the capitalist class.

From a political point of view, the theory of surplus value has been an ideological weapon for exposing the injustice of the capitalist production process. The capitalist seeks to extend the working day to extract what Marx refers to as absolute surplus value (a reduction in the value of labor power would increase relative surplus value). To this day, in capitalist economies workers suffer adverse health effects from excessive hours of work. The Japanese have their own word for it: *karoshi*—death from overwork. In response to this problem, the European Union has imposed a forty-eight-hour-maximum workweek. Marx’s theory of surplus value provides the basis for arguing for a reduction in working hours. As Philp (2005) has shown, however, the surplus-value approach does not always have to be associated with a sharpening of the class struggle. The reduction in hours can benefit capitalists if less unemployment reduces the burden of taxation.

In making the argument that workers are exploited, the problem is that on the surface, workers seem to be paid a wage for the full working day. Before capitalism, the extraction of a surplus was much more obvious. The feudal peasant gave one day’s worth of corn to the landlord, and another to the priest. Under capitalism, however, surplus value is located in the circulation of money, where workers freely exchange their labor power for wages and where capitalists seem to make profits as a natural reward for risking their money in the spirit of enterprise.

Key to the analytical power of surplus value is Marx’s assumption, maintained in the first two volumes of *Capital*, that commodities are sold at their values. The money value of consumption goods purchased by workers, using money wages, is the same as the labor embodied in those commodities; the money value of the output produced by workers is the same as the labor embodied in that output. Hence there is an assumed equivalence between surplus value, measured in units of labor time, and money profits, located in the circulation of money.

Critics of Marx, however, have argued that in *Capital*, volume 3, where he allows prices to diverge from values, the equivalence between surplus value and profits is not successfully maintained. Marx develops a procedure for transforming values into prices that is generally considered to be incomplete. Whereas the outputs of each branch of production are transformed from values to prices, the transformation is not carried out for inputs. Inspired by Piero Sraffa, and the earlier input-output approach of Wassily Leontief, Marx’s critics have shown that when the values of inputs are transformed into prices the consequences are severe. Total money profits are different from total surplus value, there being no reason why the category of embodied labor value should be at all useful. Since cap-
italists only care about money profits, why should Marxists use the irrelevant category of surplus value?

In recent years, the main reaction to this Sraffian critique of Marx has been to downplay the role of value as embodied labor time. Goods can only have value if they are sold in the marketplace, so what matters is the form that value takes in exchange—the value-form of commodities. Proponents of the value-form approach argue that in *Capital*, volume 1, Marx uses both labor embodied and value-form definitions of the value of labor power. In the “new solution” to the transformation problem, the value-form definition is preferred, with the share of wages in money income interpreted to be the value of labor power. In this approach, the equivalence between money profits and surplus value is established, even when both inputs and outputs are transformed from value to prices. A number of different variants to the value-form approach have emerged, with some dispute over the extent to which labor-embodied categories are replaced across all commodities, not just labor power, and whether the analysis should be recast in a dynamic or non-equilibrium setting (Foley 2000).

A problematic issue with the value-form approach is that by abandoning labor-embodied values, Marx’s approach is drained of all content. Is a real exploration beneath the surface offered by interpreting money categories as a form of value? There are two ways in which the value-form approach can provide a useful basis for future research.

First, by emphasizing the importance of money in Marx’s economics, it provides an alternative to neoclassical general equilibrium theory, which has limited relevance to a barter-exchange economy. The value-form approach can be used to model a genuinely capitalist system with credit money providing the vehicle for capital expansion (see Trigg 2006). The role of credit in the recent economic boom in the United States, for example, has been related to the extraction of surplus value in China. With no trade-union rights and high productivity, there is a structural relationship between the production of vast quantities of surplus value by the emerging Chinese proletariat and the credit boom associated with China’s purchase of U.S. financial assets.

Second, the value-form approach provides a possible starting point for Marxian empirical research. By working with money categories, Marxists are able to interpret national accounts data from a value-theoretic perspective. The secular fall of the rate of profit since the 1960s, which has been observed throughout the developed economies, can be empirically examined in the light of Marx’s theory of the falling rate of profit. In contrast to neoclassical economics, in which profits are assumed to be zero under perfect competition, the surplus-value approach offers a systematic analysis of how the rate of profit is determined.

SURVEY

Social scientists investigate people who lived in the past or are living in the present. Surveys are one tool they use to gather information about a population of interest. Social scientists use surveys to assess people’s behavior, knowledge, opinions, attitudes, or abilities. Surveys can be conducted orally or in written form, and they can be administered to individuals or groups. Group surveys offer an advantage over other methods of investigation, such as interviews or observation, in that they can collect sensitive data while keeping participants’ identities confidential. In addition a large amount of data can be collected at once, rather than collecting data from each participant individually. Edward Laumann and colleagues (1994) designed and administered a survey to assess the sexual behavior of American adults. The survey was administered nationwide to over 3,000 men and women, addressing such sensitive topics as typical sex practices, number of sex partners, and contraception. Two of the most important properties that must be assessed in the development and use of a survey are its reliability and validity.

RELIABILITY AND VALIDITY
Reliability is the extent to which a survey is accurate, meaning that it is free of measurement error. While this
psychometric property can be calculated using a variety of methods, reliability is theoretically the ratio of true score variance to observed score variance. It is determined by calculating a correlation coefficient on relevant data. Common methods of determining reliability include the test-retest method, in which scores from two different administrations of the same test are correlated to detect error from time sampling, and the split-half method, in which a correlation coefficient is calculated between two halves of the survey in order to determine internal consistency (Kaplan and Saccuzzo 2005).

Validity is the extent to which the survey measures what it is intended to measure or gathers the information it is designed to gather. A psychometrically sound survey is one that has been shown, through empirical research, to have several kinds of evidence for validity, such as construct-related evidence (the extent to which the instrument measures what it is claimed to measure) and content-related evidence (the extent to which the instrument includes content representative of the construct being investigated) (Mitchell and Jolley 2004). In addition to these types of evidence for validity, a survey is said to have face validity if it is obvious from the questions what the survey is designed to measure. Face validity may or may not be a desired quality for a given survey, depending on the nature of the research. That is, some surveys, particularly those addressing controversial or sensitive issues, are more effective when questions address the central topic in a covert manner. This reduces the probability of response bias, a potential disadvantage of the survey method discussed below.

SAMPLE
Once a valid and reliable survey has been designed, social scientists must administer it to people. In some situations it is possible to survey all members of the population in question. However, more often researchers are interested in a large population for which it is impossible to survey everyone. In that case, the researcher must acquire a sample of people from the population who are willing to complete the survey. To ensure the accuracy of the data, the sample should be representative, meaning it adequately reflects the actual population with regard to variables that are related to the construct(s) in question. For example, the proportion of women and men in the sample should be similar to the proportion in the population, particularly if there is reason to believe that men and women would respond differently to the survey.

There are many sampling strategies aimed at ensuring a representative sample. With the random sampling method, the sample is acquired in such a way that each member of the population has an equal chance of being selected, and the selection of each respondent is independent of the selection of all other respondents. A representative sample is important to protect research from sampling bias, the tendency for a sample to systematically exclude certain members of the population while overrepresenting others.

ADVANTAGES AND DISADVANTAGES
The survey method has advantages and disadvantages when compared to other methods of investigation. The greatest advantage of this method is the ability to collect a large amount of information from many people simultaneously. Surveys can be administered to a room full of people, a mass e-mail list, or a large telephone pool with relatively little work on the part of the researcher. A second advantage of this method is its ability to gather the exact information that is sought, since researchers write the questions they want answered. However, this advantage assumes that respondents do all of the following when completing a survey: (1) read or hear the question and interpret it as it was meant to be interpreted; (2) reflect on their personal experiences related to the question; and (3) answer the question honestly. The latter is most likely to be a problem, particularly with surveys that ask about sensitive or controversial topics. In such cases, respondents may practice impression management, wherein they answer questions so as to present themselves in a particular way. Giving socially desirable responses is a common type of impression management in which respondents present themselves in an unrealistically favorable or virtuous light. In addition to impression management, the validity of survey data may be reduced by response bias, in which respondents tend to respond to questions in a certain way (e.g., in the affirmative or negative) regardless of the actual content of the questions. Finally, because surveys are voluntary, they are subject to the willingness of respondents to complete them. Thus the response rate, or the percentage of individuals contacted who complete the survey, is important, particularly since survey response rates have declined since the early 1990s (Tourangeau 2004).

SURVEY OF INCOME AND PROGRAM PARTICIPATION

The Survey of Income and Program Participation (SIPP) is a continuous panel survey of samples of people aged fifteen and older who reside in households or noninstitutional group quarters (e.g., college dormitories, rooming houses). Each sample person is asked to provide information every four months for a period of three to four years. Information is also gathered for people who join a SIPP sample member’s household and for children in the household. The U.S. Census Bureau collects, processes, and disseminates SIPP data. SIPP began in fall 1983 and is scheduled to undergo a major re-engineering beginning with a panel introduced in 2011 or 2012.

EVOLUTION

SIPP’s origins date to the late 1960s when government program analysts became increasingly dissatisfied with the available information on household income, assets, tax liabilities, and participation in public assistance programs. A proposal in 1970 for a new income survey led to the inauguration in 1975 of the Income Survey Development Program (ISDP) in the Office of the Assistant Secretary for Planning and Evaluation, U.S. Department of Health, Education, and Welfare (now the Department of Health and Human Services). The ISDP carried out four major field tests, of which the largest and most complex was the 1979 Research Panel.

Plans to implement the full SIPP, under the sponsorship of the Social Security Administration, were derailed when funding for the program was deleted from the federal budget in 1981. The new Census Bureau director, Bruce Chapman, convinced the Reagan administration to revive SIPP at the Census Bureau. The 1984 SIPP panel began in fall 1983; it followed adult members of about 21,000 original sample households every four months for eight or nine waves of interviewing (thirty-two to thirty-six months). Another SIPP panel began each February from 1985 through 1993. A hiatus occurred until April 1996 when a new four-year panel began, followed in 2001 by a three-year panel and in 2004 by a planned four-year panel. The 1990 and 1996–2004 panels oversampled households expected to have low incomes.

The first decade of SIPP was difficult. Budget cuts necessitated reductions in sample size or in the number of interviews, or both, for the 1984–1991 panels. Conversion from paper-and-pencil to computer-assisted personal interviewing (CAPI) drove a decision to forego new panels after 1993 until 1996, when the survey design changed. Instead of an overlapping design with two or three panels in the field at the same time, SIPP adopted an abutting panel design in which one panel ends before another begins.

CONTENT AND DESIGN FEATURES

SIPP’s primary purpose is to provide detailed information on the economic situation of people in the United States. The core questionnaire in each wave asks about demographic characteristics, amounts for over seventy sources of cash income and in-kind benefits, health insurance coverage, and labor force activity (most items are asked on a monthly basis). Topical modules included once or twice in each panel cover assets and liabilities, income taxes paid, annual income, program eligibility, and personal histories. A module with variable content included once in each panel to meet the needs of federal agencies has ranged over many topics, including child-care expenses, health-care use, housing costs, child support, and extended measures of well-being.

SIPP has a true panel design in that original sample members are followed for the life of their panel, even if they change addresses, thus permitting longitudinal analysis with the core data. The current abutting design permits longer panels with larger sample sizes than the original overlapping design.

The primary products from SIPP are data files that are available via the Internet. For every panel, the Census Bureau produces files for the core data for each wave and topical module, and a longitudinal file for the entire panel. The Census Bureau also publishes occasional reports from SIPP on such topics as child-care arrangements, changes in poverty status and well-being, and the financial return to schooling. Generally, the release of data files lags considerably behind the completion of data collection for a wave or an entire panel.

ADVANTAGES AND DISADVANTAGES

SIPP is an immensely rich source of data on the social and economic characteristics of the U.S. household popula-
tion and how people’s living situations change over a three- to four-year window. Researchers have used the core SIPP data to study spells of poverty and participation in public assistance programs within and across years, the extent to which people rely on multiple assistance programs at the same time or in sequence over time, and family composition changes (for example, the likelihood of young adults leaving and moving back to their parents’ households). Researchers have used the topical module data for analyses of many issues of public policy concern.

SIPP data must be used with caution for three main reasons. First is the increasing loss of original sample members over the life of a panel, which not only is greater for low-income households and some other groups, but also has been worsening across successive panels. Thus, 32 to 33 percent of the 1996 and 2001 panels were lost by wave nine, compared with 22 percent of the 1984 panel. Second, a “seam bias” affects the monthly core data; it results because people most often report a transition, such as moving onto or off the food stamp program, at the time of the preceding interview and not within the four-month recall period of the current interview. Finally, the SIPP data are complex and difficult to use. Researchers are urged to consult carefully the file documentation, the SIPP User’s Guide, and the SIPP Quality Profile and to contact other knowledgeable users.

Compared with the Panel Study of Income Dynamics, a heavily used longitudinal survey that began in 1968, the 2004 SIPP sample is almost six times larger, and it provides intrayear data. However, SIPP has a much shorter window of observation. Compared with the Current Population Survey (CPS) Annual Social and Economic Supplement (ASEC), the source of official income and poverty statistics, SIPP has much more information and supports short-term longitudinal analyses that the CPS cannot. However, the CPS ASEC has over twice as large a sample as the 2004 SIPP panel, is released promptly, and is relatively easy to use.

SURVEYS, SAMPLE

Surveys are instruments that researchers use to measure attitudes, tastes, viewpoints, and/or facts from a specific population. Most populations (or groups) are too large and widespread geographically to allow researchers to obtain information on each group member. To compensate, researchers have devised several methods by which they make inferences about a population by using information gathered from a selected sample of the population.

Various government agencies (including the U.S. Census Bureau) and academic disciplines (including economics, political science, and sociology) make frequent use of survey sampling to better understand the prevailing characteristics of specific populations. This entry examines survey sampling through the two most common formats in which it is conducted: questionnaires and interviews. Before moving to this discussion, however, it is worthwhile to describe the central methodology that makes survey sampling of populations so effective—drawing the actual sample.

The most commonly used procedure in drawing a survey sample is the simple random sampling (SRS) method. In order to make effective inferences about a population, survey researchers must be confident that the sample they are using is representative of the population in which they are interested. If the sample is not representative then bias (the misrepresentation of a population’s characteristics) can result. SRS provides assurance that the sample represents the population because each sampling unit (a person) has an equal probability of being selected to participate in the survey.

Though an equal probability of random selection helps mitigate response bias in survey samples, most populations of interest to researchers have such significant variation that SRS alone does not provide enough confidence that the sample is truly representative of a population. In order to address population variation, national polling techniques, such as those practiced by Gallup, require an initial stratification of the population before
the random sample is drawn. Stratification is the division of a population into homogenous groups according to a specific set of dimensions or strataums (e.g., geographic location, age, sex). Once the population is divided in this manner, SRS is applied to each stratum. In most cases, survey researchers draw a proportionate stratified sample, which helps to keep the sampling units from each stratum closely resembling their proportion in the overall population. Most surveys, whether delivered in questionnaire or interview format, make use of a stratified SRS methodology.

**QUESTIONNAIRES**

Questionnaires are impersonal surveys used to collect data from respondents that have been targeted as part of a sample. Questionnaire surveys have traditionally been delivered through the mail to sample respondents. The growing popularity of e-mail in the late 1990s allowed researchers to employ this method of delivery more frequently. Despite its growing popularity, however, most survey questionnaires do not use the e-mail method because of the relatively large number of people with limited or no e-mail access as of the early twenty-first century.

The primary advantage of questionnaires, regardless of delivery method, is that they are relatively low cost. In stark contrast to interviews, questionnaires do not require the assistance of trained staff. In addition, because it costs the same to mail a survey three miles or three thousand miles, there are financial advantages to conducting national surveys. Access to bulk mail rates can provide even greater savings for researchers. Another advantage to questionnaires is that they reduce bias errors that personal interviewers may introduce. Whenever one person is talking to another to obtain information, an interpersonal dynamic is introduced that can alter the way a respondent answers questions. Since questionnaires are delivered through paper or computer, this missing human element is a welcome absence. Finally, questionnaires provide greater anonymity, in large part because there is no interviewer aware of respondent identity.

There are also disadvantages to questionnaires. Primary among these is that survey questions must be fairly simple so as to be understood by the vast majority of intended respondents. If questions are too complex or vague, respondents may miss the point of a question entirely, thereby introducing response bias. Also problematic is the inability of researchers to probe respondents for more specific information on topics. Question answers are final. In addition, researchers have no control over who actually completes the questionnaire since they have no direct contact with the respondent. Finally, researchers face low response rates (20 percent to 40 percent) when using questionnaire-based surveys. Most published research using data collected from mail surveys reports a response rate between 20 to 30 percent, although the rate is sometimes higher for targeted populations. The Internet's popularity has helped to increase response rates by allowing researchers to follow-up with respondents through a hybrid approach in which both mail and e-mail requests for questionnaire completion are transmitted to respondents.

**INTERVIEWS**

Personal interviews form the backbone of modern opinion polling. Usually conducted by a team of well-trained interviewers, these interviews enable polling companies to receive respondent data in a much shorter time frame than is required for questionnaires. Most interviews in opinion polling are of the schedule-structured variety, in which all respondents are asked the same questions, in the same order, in the same way so as to reduce response bias. Other interview forms include the focused (which allows the interviewer to ask probing questions depending upon how a respondent answers) and nondirective (in which the interviewer provides little structure or form). The focused and nondirective approaches are usually employed by academics focusing on a small sample of respondents in order to build empirical theories.

The primary advantage of the structured interview is that it gives researchers better control over the interview situation. The most direct improvement of interviews over questionnaires is that it is unlikely someone other than the respondent will provide question responses. Concomitantly, interviews have a much higher response rate than questionnaires (usually 95%), adding to their usefulness when time is of the essence. Of course, there are disadvantages, not the least of which is the interview bias referenced above. Cost is also a disincentive.

SURVIVAL ANALYSIS REGRESSION

Survival analysis is a statistical methodology to study the occurrence of an event over time. It is referred to as survival analysis because it was originally derived in contexts where the event was death, but the event under study need not be death. Examples from the social sciences where survival analysis can be used are studies that investigate time from marriage until separation or divorce and intervals between births.

A graphical representation of typical survival data is depicted in Figure 1, which shows study recruitment over time. For each of four participants, study entry is indicated as $t_0$. Occurrence of an event is indicated by a square. If no event is observed during the study period, the last known event-free time point is marked with a circle. For these participants the “time until the event occurred” cannot be specified. Such observations are said to be censored. A censored observation can arise from the fact that a participant is lost to follow-up during the observation period or from a limited observation period, that is, the event might occur some time after the observation period has ended. Censoring of this type is called right censoring. A right censored observation indicates that occurrence of the event, if it happens, will take place after the time that contact is lost with the participant or after the end of the observation period. Analysis of the data is not based on chronologic time but on a different time scale—the “time from $t_0$” (Figure 2).

Survival analysis regression aims at investigating and quantifying the impact subject and study factors have on the time until the event occurs. These factors are often measured at study entry ($t_0$) for each individual participant, and their effect on time to event is quantified via the hazard function of the survival time distribution. The hazard function models the rates at which events occur as a function of subject and study factors. Parametric and semiparametric methods are available for survival analysis regression. For details see Hosmer and Lemeshow (1999) or Kleinbaum and Klein (2005). The most frequently used model for analyzing survival data is the Cox proportional hazards model (a semiparametric model). It assumes that hazard rates are proportional over time but does not make distributional assumptions regarding survival times. Examples of parametric methods are the Weibull and accelerated failure time models, which assume specific statistical distributions for survival times in addition to assuming proportional hazards. Standard models assume independence between observations, but extensions of the models are available to accommodate dependencies (frailty models) between observations. Such dependencies might arise if participants, for example, are family members. Extensions also exist to accommodate multiple events, competing events, and factors that might change over time. On one hand the extension to multiple events and competing events is conceptually straightforward. Analysis involving factors that might change over time, on the other hand, are both technically and conceptually more involved. Survival analysis regression has been...
used extensively and successfully in various fields to quantify the impact of different factors on time to event.

SWEATSHOPS
Sweatshops, commonly defined today as workplaces violating multiple labor laws, have always been a part of the economic landscape, as have attempts to eliminate sweatshop conditions. Public outrage following the 1911 Triangle Shirtwaist fire in New York, for example, led to creation of a Factory Investigating Commission and the passage of thirty-six laws reforming the state labor code.

U.S. federal labor law is embodied in the Fair Labor Standards Act, originally passed in 1938. This act, too, responded to the prevalence of poor working conditions, calling for elimination of “conditions detrimental to the maintenance of the minimum standard of living necessary for health, efficiency, and general well-being of workers” (U.S. Department of Labor 2004, p. 1). Recent laws such as the U.S. Victims of Trafficking and Violence Protection Act of 2000 extend protection from exploitative practices.

Internationally, the 1998 United Nations Declaration on Fundamental Principles and Rights at Work provides the foundation for global labor standards. The Declaration defines four core types of labor standards: freedom from forced (trafficked) labor, nondiscrimination, abolition of child labor, and freedom of association/collective bargaining. Additional standards appear in the United Nations Anti-Trafficking Protocol, which recognizes that trafficked workers are victims of a crime and not illegal immigrants (United Nations 2000).

Despite these laws and agreements, violations of labor standards like those exposed by the Triangle fire persist and may well be increasing with globalization. In the United States sweatshop production is closely related to international flows of labor. Sectors such as agriculture, services, and clothing, in which immigrant labor constitutes larger shares of the workforce, are most likely to violate labor laws (Free the Slaves 2004).

While the extent of trade globalization as a new phenomenon is a subject of much debate (Sutcliffe and Glynn 1999), developing countries indisputably have only recently become major producers and exporters in such labor-intensive sectors as clothing and electronics. Companies in sectors that are very sensitive to wages and other costs of protecting workers may find relocation to low-wage countries a profitable response to global competitive pressure.

In developing countries, labor laws and enforcement are typically weak and labor is highly skewed toward the informal sector (Singh and Zammit 2003), defined by the International Labour Office (2002) as paid work not “recognized, regulated or protected by existing legal or regulatory frameworks” (p. 12). As a result, both wages and nonwage labor costs are lower than in rich countries. While labor costs are not always the only or even primary reason companies move out of developed countries (Chang 1998), for labor-intensive firms, moving offshore and subcontracting to informal producers clearly have become key elements of competitive strategy.

That sweatshop conditions still exist even in the United States is evidence that economic incentives for violating labor standards can be compelling to employers facing competitive threat. Opponents to sweatshops, recognizing the economic incentive to firms of low labor standards, have focused on raising the cost of using sweat labor. The International Confederation of Free Trade Unions and national trade unions emphasize ratification of and compliance with existing national and United Nations labor standards (International Confederation of Free Trade Unions 2006). Additional pressure comes from popular antisweatshop movements, often supported by trade unions, that target consumers. By exposing sweatshop producers and encouraging consumer boycotts, these movements hope to raise the cost of exploitative labor practices.

While the scope of consumer-based economic punishment of sweatshop producers is limited (Gibson 2005; Elliott and Freeman 2003), empirical evidence suggests that consumers in at least some sectors are willing to pay higher prices to support better labor conditions (Pollin,
Burns, and Heintz 2004). In clothing, popular movements have had considerable success in gaining acceptance of codes of conduct designed to raise standards. Many agreements and partnerships specifying in detail acceptable working conditions have emerged between producers and anti-sweatshop organizations representing consumers, both in the United States and in Europe.

Negotiated agreements and codes of conduct mark a dramatic step forward in recognizing basic human rights at work. A similar change is occurring in economic analysis of labor standards, with leading international institutions now linking protection of core labor standards to democracy and therefore to economic development (International Labour Office 2004; World Bank 2007).

Despite considerable progress, significant challenges remain. Government policy can have a strong impact on compliance, but mainly in large formal-sector firms (Weil 2004). Given the high level of informal labor and the difficulty of monitoring even formal-sector small producers scattered throughout the world, enforcement of laws and agreements continues to be weak.

Countries themselves raise objections to externally imposed standards, fearing loss of sovereignty and competitiveness. As one telling example, the U.S. government has ratified only two of the eight ILO core labor rights: It has not ratified the convention on the right to organize, the convention on equal remuneration, or the convention on discrimination. For poor countries, the economic consequences are not insubstantial. Some standards, such as eliminating child labor and improving health and safety, can be prohibitively expensive in competitive sectors. Even developing countries strongly in favor of raising labor standards may argue (with much evidence to support their case) that economic growth rather than outside intervention is the best path to sustainable improvement in wages and working conditions (Singh and Zammit 2003). Where intervention reduces competitiveness, growth is retarded and the intervention becomes self-defeating.

In any case, even complete compliance with existing laws and codes of conduct would not settle disagreements over sweatshops. Current laws define core standards but not cash standards (Elliott and Freeman 2003), which would mandate wage minimums designed to establish a living wage, considered by many a critical component of working conditions. Thus, although frameworks for higher labor standards are evolving rapidly, serious limitations persist. A narrow definition of sweatshops excluding cash standards and the difficulty of monitoring working conditions in an increasingly globalized economy both pose daunting obstacles to further progress. Poor countries urgently require international support to finance the improved standards that all too often they desire but cannot afford.

Symbols

Culture is based on symbols. Flags, traffic lights, diplomas, and mathematical notation are all, in their various ways, symbols. So foundational is symbolism to humans that without it communication would be impossible. The most symbolic aspect of culture is language, but symbolism also plays a role in religion, politics, art, and literature as well as in kinship, commerce, and science. Symbolism is basic to the construction and conveyance of gender, ethnic, and national identities. It is the primary way by which humans create meaning, classify knowledge, express emotion, and regulate society. The ineluctably human ability to generate and interpret symbols is, for example, what allows us to differentiate winks from blinks (Sapir 1932, p. 493). Although both are roughly identical movements involving the rapid closing and opening of the eye, the former is a meaningful gesture transmitting the conspiratorial message that the winker is in on a secret, whereas the latter is a meaningless twitch. The difference is significant but wholly symbolic. Because symbolism is fundamental to human thought and interaction, it is of concern to the social and cognitive sciences, particularly anthropology and linguistics, though it is also studied by psychology, philosophy, and sociology, and to a lesser extent political science and even economics.

At its most basic level, a symbol is anything that represents another thing by virtue of customary association due to a conceptual connection or perceived resemblance. The English word symbol derives etymologically from the Greek σύμβολον, meaning “tally,” “contract,” or “ticket,” which referred originally to a token that was broken in two so that each half could be used to confirm the identity of the other. The word stems from the Greek roots syn- (“together”) and ballein (“to throw”), and thus has the approximate connotation of “to throw together.”

Universal versus Culture-Bound Dimensions of Symbolism

Because virtually anything can serve as a symbol and because a symbol conveys information only in so far as it has meaning to a specific community, the connection between a symbol and its referent is not intrinsic to the symbol itself but rather is a function of agreed upon use, custom, or convention. It is in this sense that language is symbolic. The word water designates the liquid object only insofar as members of the English speech community agree that it does. The liquid has no inherent property that compels us to call it by that name. It could just as well be designated by other sounds, for instance agua in Spanish, mayim in Hebrew, or vo’ in Tzotzil Maya. Exceptions to this arbitrariness may exist in ethnobiological classification (see Berlin 1992) and onomatopoeia.

The meaning of political and religious symbols, often charged with emotion, are likewise dependent on cultural contexts, even when the same or similar signs are employed across cultures. For Christians the Eucharist is a holy sacrament symbolizing the Body and Blood of Christ, yet pagans may see the consumption of bread and wine as a representation of ritual cannibalism. Or again, the swastika has come to be taboo in much of Europe and the United States due to its historic association with Nazi Germany and contemporary white supremacists, but elsewhere, as in the cases of Hinduism, Buddhism, and Native American religions, it remains a sacred symbol with positive connotations. In religions of Indic origin it is a symbol of auspiciousness, as reflected by its original Sanskrit name svasti, meaning luck, well-being, and fortune; in Hindu traditions it is a solar symbol, and in Buddhist regions it adorns the entrance to some temples. The swastika design is also seen in Native American traditions. To the Navajo the symbol is known as the “whirling winds,” and was used in curing ceremonies, and as a motif.
Symbols

woven into textiles; among the neighboring Hopi it was a conventional sign associated with clan migrations. In short, symbols are without specific meanings aside from the connotations assigned to them.

Depth Psychology Still, certain studies suggest that some symbolism is universal, due to its rootedness in unconscious processes, developmental stages, or panhuman experiences of the body, eating, and sexuality. Sigmund Freud (1989) maintained that the symbolism found in dreams, myths, fairytales, and linguistic utterances expresses in disguised form unresolved childhood conflicts or taboo urges surrounding sexuality and violence that are repressed in the subconscious of individuals. Jung (1964) viewed certain symbols as archetypes of the “collective unconscious.” Thus, one encounters universal archetypes—the Trickster, Rebirth, the Hero’s quest, the Great Mother, and so on—not only in the myths and rituals of tribal peoples, the art of the high Renaissance, and modern science fiction, but also in the dream-work, projective fantasy, and free-associations of the patient involved in psychotherapeutic individuation.

The Human Body Many researchers have posited that the human body provides a template for another set of experiences held in common by all people. Throughout the world, pre-eminence is accorded to the right-hand side in systems of lateral symbolism and dual classification (Needham 1973), while hair is freighted with multiple symbolic meanings and therefore is a focus of ritual in almost all societies. The fact that the same three colors predominate in ritual symbolism cross-culturally may reflect a psychobiological substrate: the common experience of body fluids, through which black is linked to feces, white to semen or breast milk, and red to blood (Turner 1967). However, a caveat is warranted here, for these colors are also worked through local categories of meaning. While black may be associated with feces and therefore ideas of pollution, night, and death in many cultures, in Hinduism it is white, not black, that is associated with death, funerals, and mourning.

Others have suggested that the human body is a “natural symbol” for any bounded system, not least of them the well-known organic model of society, in which the categories of the physical body provide the model for the experience of the social body and vice versa (see Douglas 1970).

Alimentary Classification Food constitutes another universal plane of symbolic classification. Claude Lévi-Strauss, who founded the structuralist approach to the analysis of symbols, theorized that the opposition between raw food and cooked food, elaborated symbolically in myths and rituals around the world, is an expression of the universal dichotomy between Nature and Culture (1970). Because in all societies people must not only eat but also marry, he overlays the rules of kinship and marriage on the classification of food. Building on the idea that the boundaries of the natural body and social body reinforce each other reciprocally, Lévi-Strauss demonstrates that eating and intercourse are symbolically equated (although not always consciously) in many societies, making culinary and sexual codes mirror images of each other (1966). In a related vein, Mary Douglas famously argued that the dietary laws in the Old Testament reflect a typology in which the animals prohibited as food to the ancient Israelites were taxonomic anomalies that cross-cut the socially construed ideal categories of creation just as “mixed marriages” were prohibited because they similarly would produce “hybrid” children that transected the ideal social divisions ordained by God (1966).

TERMINOLOGY AND THE LOGIC OF SYMBOLISM

The study of symbolism deals with two different but related issues. One concerns what symbols mean, the other how they work, or the logic by which they come to mean anything in the first place. Analysis depends on a differentiation between signifier (the perceptible vehicle or external form), signified (the meaning, referent, connotation, etc.) and signification (the relation between the two). Some scholars, such as Clifford Geertz, use the word symbol as a blanket term “for any object, act, event, quality, or relation which serves as a vehicle for a conception” (1973, p. 91). Yet because the word symbol has been used in an enormous variety of ways, other researchers find it necessary to distinguish between symbol, sign, and signal, sometimes making further distinctions by adding index and icon to the list. Despite a large literature on the topic, there is, however, a lack of uniformity as to how this terminology is employed. Still, if one considers the distinctions between symbol, sign, and signal to represent differences in degree rather than kind, there is some consensus as to the way the definitions are drawn.

Signal, Sign, and Symbol A signal generally expresses a relationship between signifier and signified that is dynamic or causal. Animals as well as humans make use of signals, and in both cases the signifiers trigger or incite certain actions—as, for instance, when a male bird arouses the female by signaling with a mating call or car brake lights signal motorists behind to stop. A sign tends to have a singular meaning, in that signifier and signified are closely connected and typically come from the same context, and the signification itself is mostly metonymic—that is, a part or attribute stands for the whole. When, for
example, a hunter sees a hoofprint of the deer he is pursuing, the hoofprint is a sign of his quarry. In military, technical, and commercial fields signs are often employed as codes, such as Morse code or the North American Industrial Classification System used to designate business type. When signs are used as codes it is because the relation between signifier and signified is conventional rather than intrinsic and because the signification is precise.

Symbols expand the notions of signs and signals. Symbols are characterized by rich meanings that are multiple, fluid, diverse, layered, complex, and frequently predicated on metaphorical associations that assert an analogy between things from different contexts that normally may not be connected. Given that the referents of symbols tend to be general, abstract, and ambiguous, their personally or socially constructed significations may not be apparent except to those who make them.

Whether a signifier is a symbol, signal, or sign is determined not by the object itself but rather by how it is used. In fact, the same signifier can function as all three depending on the situation; for example, the color red functions as a signal in stoplights, as a sign of blood in a painting of the crucified Christ, and as a symbol in a national flag. Moreover, the meanings of symbols, insofar as they are conventional, are context-dependent and variable, both across and within cultures. In ancient Rome red was associated with the god of war, Mars, whereas in China red is an auspicious color associated with luck, money, success, happiness, and traditional wedding attire. In the United States, a red rose is a statement of love, but being “in the red” means one has suffered economic losses, and “seeing red” means one is angry.

Icons and the Problem of “Likeness” Symbols are usually iconic—that is, “a sensory likeness-relation is intended or interpreted” (Firth 1973, p. 75). Of course, from an anthropological perspective, what is seen as the associated or analogous “sensory likeness-relation” between signifier and signified is culturally determined; as Victor Turner appositely remarks, “one culture’s analogy is another culture’s puzzle” (1975, p. 151). Therefore, because iconicity is culturally constructed, many scholars prefer to use the term icon only when there is a geometrical similarity between signifier and signified, as with formal pictures, portraits, or models. Typical icons of this sort, which often involve a change in scale between signified and signifier, include maps, the Roman numeral II, and religious images of the Buddha, Christ, and saints.

While such icons clearly manifest likenesses, or analogous qualities, much symbolism rests on the predication of resemblance between things that are neither ostensibly similar nor physically in contact. Even science relies on symbolism when, associating things that are profoundly unlike, it uses analogies to explain causation, whereas magic uses analogies to connect unlike things through associations of co-occurrence.

Metaphor and Metonymy A distinction between metaphor and metonymy is basic to symbolism. Metaphor is “principally a way of conceiving one thing in terms of another, and its primary function is understanding.” Metonymy, on the other hand, has “primarily a referential function, that is, it allows us to use one thing to stand for another” (Lakoff and Johnson 1980). Metonymy is a form of signification in which an attribute or name of something is used to denote the wider semantic field to which the thing belongs, signifier and signified being drawn from the same general context. Thus, the word brass is a metonym for “military officers,” just as crown is used metonymically for “kingship.” Metaphors, on the other hand, are comparisons, similes, or analogies, and rely on a sensory resemblance or asserted conceptual similarity between things belonging to different cultural contexts, and imply the transference of qualities from one context to another. For instance, when a brand of beer uses a crown on its label to assert that it is the “king of beers,” it is making a metaphorical association, as royalty and alcoholic beverages belong to different domains (Leach 1976, p. 14). Metonyms and metaphors, like signs and symbols, frequently co-occur in the same communicative event, with one level of meaning characteristically being played off the other.

FEATURES OF SYMBOLIC COMMUNICATION

Symbols are especially useful in showing what one cannot say; that is, they express ineffable concepts, abstract ideas, and particularly complex emotional significations that are difficult or impossible to fully articulate. Because they powerfully sum up many things at once, symbols are frequently deployed in political and, especially, religious domains. While the existence of different political parties shows that not everyone agrees about what their country stands for, everyone does agree that their country’s flag stands for their country. One way in which symbols can be used to condense a constellation of meanings is through the invocation of physical attributes that are associated with moral character: The “straight” or “upright” man can be contrasted with a man who is “crooked” or “low.”

Multivocality Symbols predominate in political and religious contexts because their wide spectrum of connotations, which permits multiple understandings among subdivisions within a population, allows them to appeal to a broad audience. The more public a symbol is, the wider is its range of referents—and the broader its range of signification, the richer and more complex its meaning.
Symbols

becomes, allowing for diverse and sometimes even contradictory interpretations. "Key symbols" (Ortner 1973), those that characterize whole peoples, nations, religions, and political movements, tend to be among the most abstract and polysemous, yet still provide basic orientations for thought and action—such as with the Virgin of Guadalupe, who is used to symbolize Mexico.

The radical polysemy of symbolic signification led anthropologist Victor Turner to conclude that an outstanding feature of all symbols was what he termed their multivocality, that is, "they stand for many objects, activities and relationships; there is not a one-to-one relationship between symbol and referent but a one-to-many relationship" (1967, p. 284). According to Turner, one must consider three fields of meaning: the exegetical meaning, or what members of the culture say the symbol means; the operational meaning, revealed by how the symbol is used; and the positional meaning, which derives from the relation between a symbol and other objects and symbols in the same or related cultural complexes (pp. 20, 284–285). Symbols are further characterized by a polarization of meaning (p. 28), one pole having to do with the symbol’s sensory aspects or the emotional impulses it arouses, the other indexing related normative values or principles of ideology or social organization.

The Logic of Binary Oppositions For Lévi-Strauss in his studies of symbols in myth, totemism, and other systems of symbolic classification (1966), symbols cannot be interpreted as having meaning in themselves but only in terms of structural opposition, a binary logic that exists in culture because it is in fact a reflection of the binary structure of the human mind. Drawing intellectual capital from the structural linguistics of Saussure (1966) and Jakobson (1956), as well as mathematics and the natural sciences, Lévi-Strauss reasoned that meaning was created symbolically in culture in a way that was analogous to the way it was created in information theory and in language. In the digital world of computers, everything from words to pictures to music is based on a binary logic that involves only two numerical symbols, 1 and 0. In linguistic phonetic analysis, meaning comes about through discerning phonetic differences within minimal pairs. For instance b and p in English are both labial stops, the only difference being that the former is voiced and the latter is not, yet it is that minimal difference that allows us to differentiate between a bat and a pat. So too, in culture, symbols have meaning because they also are based on binary oppositions—raw/cooked, hot/cold, high/low, rough/smooth, light/dark, right/left, and so on—that reflect sensory contrasts and ultimately relate back to the primary symbolic opposition between nature and culture. Moreover, not just oppositions but also the logical relations between sets of oppositions are important to the analysis of symbolic systems. These logical relations may be expressed in terms of reciprocity, analogy, homology, reflection, inversion, isomorphism, and so on.

Models of and Models For Another anthropologist, Clifford Geertz, took his cues not from the sciences but instead from literature, philosophy, and the humanities generally. He takes an “interpretive” approach to culture, which in his view is essentially a system of symbols, the analysis of which is akin to formulating a critical reading of a manuscript or interpreting a poem, as culture itself is likened to an assemblage of texts. Geertz proposes that “cultural patterns, that is, systems or complexes of symbols” are artifacts in the public domain; they are not private cognitions or meanings accessible only through the specialized techniques of psychologists and philosophers (1973, pp. 91–92). Geertz also holds that cultural patterns are models composed of sets of symbols whose relations to one another “model” relations among other psychological, social, and physical entities, activities, processes, and so forth by paralleling or simulating them. Geertz’s most novel insight, however, comes from his observation that the term model has two senses, an “of” sense and a “for” sense, and it is this dual aspect that gives symbols their special quality, for when they are configured together into cultural patterns they are both a model of reality and a model for reality; that is, they both reflect the world and shape it. If one sees religion as a “cultural system,” as Geertz does, and as a complex of symbols, then the models on which these constructs are based have this dual aspect in that they both describe the world as it is and prescribe the way it ought to be.

Multiplex and Transflective Displays Symbols display two other noteworthy characteristics: They are multiplex as well as transflective. Both ideas derive from the electrical sciences. As used in electronics, telecommunications, and computer networking, the term multiplex refers to the simultaneous transmission of two or more signals along one communications channel or the sharing of information in a single medium. Symbols can be thought of as wires or channels. When, for example, a man sends a red rose to the object of his affection, two messages symbolizing love are being communicated simultaneously through the same communications channel, yet they are being modulated via different sensory receptors (namely, vision and smell): The red color connotes the heart and passion and the scent connotes the sweetness of romance. This multiplex modulation or sensory fusion causes many symbols, especially metaphors, to evoke experiences comparable to synesthesia—the coupling of different bodily sensations or the crossing of sensory wires—compelling persons to hear colors, taste sounds, or in the case of the rose, simultaneously see as well as smell something felt.
The term transflective is used in electrical engineering to refer to a type of liquid crystal display (LCD) screen in which the pixels are illuminated from both the front of the monitor’s screen by ambient light and from behind the screen by an internal light. Analogously, symbols, especially in ritual, are regarded as both transmitting and reflecting the spiritual effluence that animates them and makes them foci of intense cultural meaning. A symbol is “illuminated from behind” in that it transmits general meanings, moods, energy, and radiance from a source that is internal to it—that is, from a power that is “within” or “behind” the symbol. It is also reflective, or “illuminated from the front,” in that it absorbs the particular conditions, meanings, emotions, and intentions projected onto it in a particular moment and reflects these back out again. In the study of ritual, one can think in terms of the dual illumination coming from and reflected on the Christian cross, or coming from and reflected on quartz crystals used in Navajo rituals. In varying degrees all symbols, but especially sacred symbols, both transmit public meanings and reflect private ones, and it is this dual aspect that makes them boundless sources of meaning, energy, and significance.

**SYMPATHY**

Sympathy is an emotional response that involves both understanding and being moved by the suffering or joy of another. Perhaps the most famous illustration of this response occurs in the biblical parable of the Good Samaritan, where a certain Samaritan stops to help a man left half dead by thieves on the way from Jerusalem to Jericho. Sympathy, then, as this parable suggests, is a kind of positive response to another’s suffering and is distinct from other negative responses, such as schadenfreude, a kind of joy or pleasure at another’s misfortune. Further, sympathy, as we commonly understand it, is also distinct from empathy—although this distinction is not always observed. Empathy involves the sharing of another’s feelings or the processes by which we come to feel as another feels. Sympathy, in contrast, involves, first, an awareness of another’s suffering as theirs and not ours and, second, being moved to relieve that person’s suffering.

To talk of “positive” and “negative” responses to the suffering of others indicates yet another widely attributed (though contestable) feature of sympathy: that it is a kind of moral emotion or response. Sympathy, or equivalently now compassion, understood as a kind of moral response to the suffering of another, has had a significant influence on moral thought and practice, specifically in the moral theories of several modern philosophers, including in the eighteenth-century David Hume and Adam Smith, in the nineteenth-century Arthur Schopenhauer, and in the twentieth-century Max Scheler. Such figures, however, do not necessarily understand sympathy quite as we would.
Hume, for instance, sees sympathy as a kind of mechanism through which the feelings of others are transferred to us (the two analogies he uses are the reverberation of sound and the reflection of light in a mirror), which seems closer to empathy as described earlier.

The idea that sympathy is an attribute important to morality extends, however, beyond the modern world. One obvious earlier reference to sympathy as a morally significant attribute comes to us from Buddhism, though this is hardly the only one. One explanation of why sympathy should feature in the moral thought and practice of different cultures is perhaps that human suffering is such a basic evil that its relief (except in certain highly specific circumstances, such as those related to criminal punishment) is thought across cultures to be an unqualified moral good. Even in societies where sympathy does not figure prominently in moral thought and practice (as was plausibly the case in various ancient societies, including ancient Greece and Rome), it would generally still be recognized as an important human quality in some sense. A person completely devoid of sympathy would in almost any human society be viewed as lacking a critical human attribute—indeed in terms of modern psychological categories, we would describe such a person as a sociopath, a person devoid of any moral sense or conscience.

Sympathy, then, seems to be a fundamental human psychological attribute or state. Indeed its presence seems central to normal human psychological development. Even infants, for example, become distressed at witnessing the distress of others. While this response may simply be an early form of empathy, it seems plausible to suggest, as some psychologists have done, that sympathy as a more cognitively complex emotional state develops from this simpler emotional response. Thinking of the development of sympathy as a part of normal human psychological development may then be thought to provide support for a kind of naturalistic explanation of morality. It is our natural capacity for sympathy (a capacity that we develop from infancy to adulthood) that makes certain moral cultural practices—including, for example, our recognition of claims on us derived from other’s needs—possible. But while a number of moral philosophers (including Hume and Smith) have advanced moral theories in which sympathy plays something like this naturalistic explanatory role, other moral theorists, most notably those influenced by Immanuel Kant, would deny that sympathy has this sort of moral foundational role. According to the Kantian view, morality is founded not on our emotional capacities but on our capacity for reason alone.

SYNDICALISM

Syndicalism—and its cognates, known as anarcho-syndicalism or revolutionary syndicalism—was a radical movement linked to the rise of trade unionism and socialism in the late nineteenth and early twentieth centuries. Syndicalists traced their origins and beliefs to Marxian political thought. They believed that in society and the economy there was a split between capitalists (employers) and labor (workers) and that these two contending classes were engaged in a perpetual struggle over the proper division of an economy’s total product. Syndicalists and socialists maintained that the class struggle between capital and labor would persist until workers seized the full fruits of their productivity by eliminating production for profit. Syndicalists differed from socialists in their insistence that workers could liberate themselves from capitalism only through self-activity and direct action at the point of production, without resort to politics and legislation. Syndicalists shared with trade unionists an ideology that stressed worker self-activity and direct action above politics and parliamentarianism; indeed, the term is derived from syndicat, the French word for trade union. What most sharply distinguished syndicalists from other trade unionists was the former’s commitment to the abolition of capitalism through revolutionary direct action.

Syndicalism achieved its largest membership and peak influence between 1905 and 1919. The first workers’ organization to adopt a syndicalist program was the French Confederation Generale du Travail (CGT), which in its 1905 Charter of Amiens declared its autonomy from the Socialist Party and other political bodies that sought parliamentary representation. Instead of seeking to advance workers’ interests through electoral activity and legislative reforms, the CGT called upon its members to combat their class enemies through direct action on the job. That
same year a select group of radicals in the United States created the Industrial Workers of the World (IWW). At its 1905 founding convention, the IWW included members of the Socialist Party of America (SPA) and the Socialist Labor Party among its most prominent delegates and platform speakers, but by 1908 the organization had severed all formal relations with socialism and other political parties. During the same years, syndicalist organizations emerged in Germany, the Netherlands, Scandinavia, Great Britain, Italy, Spain, Argentina, Chile, and Mexico, among other places. Yet except for France, Italy, and the Spanish-speaking nations, syndicalism represented only a minority tendency within a much broader worker and radical movement. This was especially true in those nations with more developed economies and powerful trade union movements, such as Germany, Great Britain, and the United States. In Germany, syndicalism was overshadowed by the Deutsche Gewerkchaften Bund (DGB) and the Socialist Party (SPD). In Britain, syndicalism existed largely as the personal cause of a single prominent labor leader, Tom Mann, whose Industrial Syndicalist Education League published pamphlets but lacked members. And in the United States, the IWW rarely built a substantial membership. Only in France, Italy, Spain, and the Latin American nations, which all had far smaller and weaker labor movements, did syndicalism emerge as a dominant tendency, and even in these nations it existed more clearly among leaders than followers.

Between 1905 and 1913, no transnational or international body united the movement's separate national manifestations. Yet syndicalists shared a common ideology and common strategy and tactics. Moreover, syndicalists regularly crossed national borders to promote their cause. Tom Mann traveled often to Australasia, South Africa, and North America; the American syndicalists William D. Haywood and William Z. Foster visited Britain and France; and French, Italian, and Spanish syndicalists crossed their respective borders and traversed the Atlantic. A common set of ideas and assumptions united all syndicalists. Whether they claimed to find their original inspiration in the French anarchist Pierre Proudhon's tirades against property and the state or Mikhail Bakunin's battles with Marx and Engels about the role of political parties and the state, they insisted that workers must liberate themselves from capitalism through direct action, with the strike as the workers' most effective weapon.

For a syndicalist, no strike brought failure or defeat. If workers won their struggle, they learned the lesson of solidarity and worker power. If a strike failed, they discovered that employers were their enemies and that class struggle remained the essence of existence. Thus, even defeated strikers could return to their jobs without relinquishing the class struggle. Back on the job, workers could harass their employers and diminish their profits by strictly applying work rules to slow production, declining to use inferior materials, refusing to maintain machines in optimum condition, regulating the pace of work, and, in some instances, damaging the machinery, tools, and goods with which they worked. Syndicalists defined these tactics as “sabotage,” and they taught workers concrete lessons in the application of their power, without casting ballots or seeking legislative reforms. Indeed, syndicalists believed that as workers assimilated the lessons of direct action and applied them in practice, they could eliminate capitalism. The culmination of direct action would be the social “general strike,” in which all workers left their jobs or laid down their tools simultaneously, paralyzing the economy and demonstrating that labor, not capital, wielded power. In the aftermath of the general strike, workers' organizations would administer the economy, eliminate production for profit, and reorganize the economy. As a result, political parties and the state would vanish.

In 1913 the separate national syndicalist movements united to create their own international body, a counterpart to the socialist Second International. And like the Second International, the Syndicalist International failed to survive the outbreak of World War I (1914–1918). Another result of the war—the Bolshevik Revolution in Russia—brought more grief to syndicalists. Most syndicalists initially found vindication in the triumph of the Bolsheviks, which they perceived as a victory for workers. Indeed, syndicalists considered the Soviets to be the Russian version of the self-governing workers' institutions that would govern society and economy in the aftermath of revolution, and they enlisted enthusiastically in the Comintern and its trade union affiliate, the Profintern. But as Lenin and his comrades established their dictatorship of the proletariat and used the party and the state apparatus to dominate the new Soviet Republic, many syndicalists felt that the Bolsheviks had subjected workers to new forms of subjugation. Other syndicalists, such as Mann and Haywood, remained loyal to the Bolshevik cause. A majority of syndicalists, however, including the anarchist Emma Goldman, served as the most vitriolic critics of the Bolshevik dictatorship.

In 1923 the anti-Bolshevik syndicalists formed a second Syndicalist International. By then, however, the separate syndicalist national movements formed, at best, marginal and often minuscule worker movements compared to the dominant trade union movements. In Britain, syndicalism disappeared as a living presence, while in Germany, the Netherlands, Scandinavia, France, and the United States it survived as a marginal, minority movement. Only in Spain did syndicalism—in its anarch-syndicalist form—maintain a vital presence. Here, it dominated the national labor movement until its crushing defeat by Franco and the Falangists in the Spanish Civil War of the 1930s. Since then, wherever syndicalism has
survived, it has done so solely as a concept of worker self-activity esteemed by small circles of intellectuals or as a minuscule movement among workers.

SYSTEM ANALYSIS

System analysis, system inquiry, or systems theory is the study of the interdependence of relationships. A system is composed of regularly interacting or interrelating parts that, when taken together, form a new whole with properties distinct from its constituent parts. Systems are seen to be structurally divisible but functionally indivisible wholes with emergent properties. Central to system analysis is the recognition that the structure of any system—the many interlocking, sometimes time-delayed, sometimes circular interrelationships among its components—is often just as important, if not more important, than the individual components themselves in determining the system’s behavior.

Systems are characterized by complexity, a set of boundaries, and the ability to regenerate. Complexity refers to a large number of densely connected parts and multiple levels of embeddedness and entanglement. A system is defined by a set of parametric conditions or boundaries that delimit it or set it apart from its environment. No system can be completely closed or else we could not perceive it; there are only varying degrees of closure set by boundaries. A system regenerates itself through the self-reproduction of its own elements and of the network of interactions that characterizes them in a process known as autopoiesis. Thus an autopoietic system renews, repairs, and replicates or reproduces itself in a flow of matter and energy.

Systems can change through an evolutionary process with a tendency toward greater structural complexity and organizational simplicity, more efficient modes of operation, and greater dynamic harmony. Change is enacted through a process of feedback where information concerning the adequacy of the system, its operation, and its outputs are introduced into the system. Negative feedback signals that there is a discrepancy between what the system produces and what it should produce. It tells us that we should change something in the system so that we can reduce the deviation from the norms stated in the system’s output model. Positive feedback signals that the whole system should change, that we should increase the deviation from the present state and change the output model. Functionalism is based on this adaptation. To survive or maintain equilibrium with respect to its environment, any system must to some degree adapt to that environment, attain its goals, integrate its components, and maintain its latent pattern, a cultural template of some sort.

A system can be ordered as a hierarchy or a heterarchy. A hierarchy is a vertical arrangement of entities within systems and their subsystems. A heterarchy is an ordering of entities without a single peak or leading element, and which element is dominant at a given time depends on the total situation. Systems may be understood through holism, where attention is focused on the emergent properties of the whole rather than on the behavior of the isolated parts, or reductionism, where phenomena are understood by breaking them down into their smallest possible parts.

Several fields utilize system analysis. Cybernetics, chaos theory, and social dynamics, for example, are among the disciplines that apply system analysis. Some areas of education and environmental sustainability also utilize system analysis. The systems framework is also fundamental to organizational theory, as organizations are complex, dynamic, goal-oriented processes; in anthropological studies, notably those incorporating positive and negative feedback; and in cybernetics, catastrophe theory, chaos theory, and complexity theory, all of which have the common goal of explaining complex systems that consist of a large number of mutually interacting and interrelated parts. In biology the living systems theory of James Grier Miller is a general theory about how all living systems work, maintain themselves, develop, and change. Living systems can be as simple as a single cell or as complex as a supranational organization such as the European Union. In sociology the structural functionalism of Talcott Parsons argues that the largest system is “the action system” consisting of interrelated behaviors of individuals, embedded in a physical-organic environment with others, with each part in a social system arranged in a pattern of interpenetrating relationships influenced by a socializing culture that constitutes standards and channels for guiding actions. Societies (which are highly complex), like systems and organisms, have functional needs that must be
met if the society is to survive. Parsons says that all societies have four basic needs: adaptation, goal attainment, integration, and pattern maintenance (i.e., inertia, latency, or self-maintenance).

The deterministic or restrictive nature of systems is addressed by aspects of structuralism. Structuralism rejects the concept of human freedom and choice and focuses instead on the way human behavior is determined by various structures. Thomas Kuhn, for example, notes how scientists operate under a standard praxis of “normal science,” deviating from a standard “paradigm” only in instances of irreconcilable anomalies. In political science the structural realism of Kenneth Waltz describes international politics as a systemic interaction of states within an anarchical environment. States first seek survival and are socialized by an anarchical environment to act and react based on threats to survival and to form self-help alliances with like units. The system effects described by Robert Jervis notes how political relations among states in a system, similar to biological interactions among cells and other scientific phenomena, can produce effects different from the sum of individual actions.

SYSTEMS THEORY

Systems theory is a philosophy and worldview arising from the belief that aspects of the world are not independent of each other but interdependent on one another. This results in a research view and approach that it is difficult if not impossible to separate components of a question from logically related material in the world at large. “Logically related” depends on the question under examination and changes as the research question changes. Systems theory is sometimes called structural functionalism or holism.

Systems theory approaches understanding a problem as understanding a set of relationships among disparate factors. This contrasts to classic scientific analysis, where a set of independent variables is compared to dependent variables. Examining interactions among the independent variables approaches but is not systems theory. Systems theory requires two things. First, there must be a web of interactions among all the elements under study. Second, there are complex patterns as a result of these interactions. Sometimes systems theory includes such concepts as feedback systems and chaos theory. However, not all systems theorists include these research approaches within systems.
theory. Organizational and social network research is included in systems theory.

Because of the interactions among components, systems analysis tends to involve more complex analytical techniques. For example, instead of least squares analysis, systems theory might employ computer modeling and simultaneous equations techniques. System theory’s strength and weakness arises from this. The methodology is harder to learn and understand, but the explanatory power can be greater. Also systems theory tends to be interdisciplinary, especially in the social sciences. A planetary system can be isolated for study and still be a system. The reasons behind results in a particular election can involve individual and group psychology, economics and market analysis, history, religion, and communications theory because all of these are known electoral factors.

This can lead to the complaint that systems theory overcomplicates problems and research. This complaint is not without some validity. In certain analysis situations systems theory can be overkill. In other situations systems theory can be necessary for understanding the problem.

The basic concept of systems theory can be traced back to philosophers in ancient Greece and China. As a research approach, systems theory is much more recent. Modern systems theory dates to just after World War II and such researchers as Margaret Mead and Gregory Bateson. Their work is based on concepts developed by Rudolf Virchow, Adolf Bastian, and Franz Boas. In turn this work is based on the philosophic concepts of G. W. von Leibniz in the 1600s. Modern systems researchers include Niklas Lehmann and Robert Axelrod.

Simple systems in modern use include such things as the feedback concept of a household thermostat that turns on or off a heating or cooling unit depending on the temperature inside, the temperature outside, and the desired temperature. Complex systems include chaos theory and its applied forms in different disciplines.

David Conklin
The term *taboo* is derived from a Micronesian word that means “reserved” and originally alluded to objects or things that contained so much supernatural power that only trained religious specialists could handle them safely. The word *taboo* was first mentioned as a native term in Captain James Cook’s (1728–1779) accounts of his voyages to the Pacific islands. It quickly entered English popular usage and has been used in comparative anthropology since then. This conception of taboo is illustrated in Old Testament accounts of laypersons who were afflicted with disease or even killed on the spot after touching the sacred Ark of the Covenant. More generally, however, the term is used to describe a wide range of vernacular beliefs that forbid certain actions for fear that they will lead to a catastrophe afflicting the surrounding community. The seeming disparity between the apparent triviality of the forbidden actions and the extent of the feared consequences distinguishes taboos from the more pragmatic magical beliefs describing contraindicated actions with certain consequences. Psychoanalyst Sigmund Freud (1856–1939), in his influential collection of essays *Totem and Taboo* (1912–1913), also adapted *taboo* to refer to a form of compulsive behavior among modern-day persons.

The most common and best-studied taboos deal with sexual and dietary precautions and may well derive from pragmatic experience. One of the most widespread categories of taboos concerns limiting marriage to partners outside of one’s family or clan. The myths explaining these taboos tend to portray the associated disaster in terms of a divine punishment, as in a Zuni myth that associates a catastrophic flood with inbreeding within clans, or the well-known Greek myth of Oedipus, whose unwitting marriage with his mother was the cause of a decimating plague. However, given the ubiquity of such taboos, it is clear that they were based on prescientific observations linking genuinely risky actions to cultural misfortunes that occurred later. It took no knowledge of genetics to recognize that inbreeding among family or clan members was associated with a higher rate of lethal birth defects and genetic illnesses.

Similarly, many dietary restrictions may be based on a recognition that close contact with certain food animals, especially pigs, was associated with a wide variety of diseases, some (like trichinosis) parasitic in nature, others (like influenza) communicated directly from live animals to susceptible humans. However, as Mary Douglas (1966) noted, such food taboos are often associated with images of the culture’s own identity. Thus a meal such as the “kid seethed in its mother’s milk” (the basis of the kosher division between dairy and meat products), may have been in origin a ritual meal of a rival culture. Hence both marriage and dietary taboos became, in practice, ways of maintaining the boundaries of a culture’s membership.

Taboos are often enforced by institutional religions, frequently through dominating secular institutions. In Islamic cultures, religious taboos against the consumption of alcohol and indiscreet behavior by females are strongly enforced by secular authorities, even among non-Islamic visitors. Similarly, restrictions on certain forms of incestu-
ous marriage are normally written into legal codes. But many cultures add to these codes prescriptions against other forms of marriage, such as interracial or same-sex unions, which involve no risk to the partners or their cultures but which are seen as irreligious and so dangerous to the safety of the commonwealth.

However, many taboos are privately enforced, especially among those practicing professions with high degrees of danger or risk, particularly sailors and miners. Violating such a taboo may lead to a spontaneous work stoppage by coworkers, who fear risking a serious accident. A number of these taboos reflect vernacular understanding of religious practices. The Jewish restriction on work during the Sabbath clearly underlies the common superstition taboeing the start of any major project (such as a ship’s voyage) on a Friday because the work involved would usually stretch past sundown and so into the forbidden time. The proscription on speaking the sacred names of God, particularly in private rituals of magic, is commonly extended to purely mundane uses of divine words in trivial oaths and exclamations. However, many other words, such as pig (often forbidden in mariners’ conversations) may show an extension of the dietary taboos into the realm of language. Other taboos, such as miners refusing to work on a day when their hands or feet were unusually cold on rising (the origin of the proverbial phrase “got cold feet”) may reflect popular psychology. The common taboo on allowing women to participate in such risky professions, or even to be present onboard ship or in a mine shaft, is probably linked to the common practice of soldiers and male athletes avoiding sex before action, originally a religious act of renunciation in return for divine favor and increased strength.

An especially widespread class of taboos reflects cultural attitudes toward death. Many such practices forbid the explicit mention of dying or overly free use of objects associated with funerals. Hence, in Japan the number four (pronounced “shi,” which also means “death”) is a common taboo, being omitted in hospital rooms and flight numbers. Similarly, in Italy, the number seventeen is often skipped because it could be expressed in Roman numerals as XVII, which is an anagram of the Latin past perfective verb “VIXI,” which literally means “I have ceased to be alive,” or, more bluntly, “I died.” Flowers associated with funerals, such as lilies (in North America) or chrysanthemums (in Asian countries), should not be given to the living for fear of putting them at risk. Common legends assert that wearing an article of clothing worn by a corpse may lead to one’s own death, and buildings or even automobiles in which death occurred may become too contaminated for the living to use. Behind all of these taboos is the belief, especially strong in Western cultures, that the living need to be insulated from the concept of mortality.

Overall, taboos are best understood as parallel to magic: magical actions are ways of managing one’s perception of risk or danger by doing something, whereas observing taboos minimizes risk by not doing something. Of course, refraining from a tabooed action often involves choosing actions with religious and magical overtones (such as the preparation of kosher meals).

**TAINO**

The Taino Indians are a subgroup of the Arawakan Indians of northeastern South America. They were living in the Greater Antilles (Hispaniola, Jamaica, Cuba, and Puerto Rico) when Christopher Columbus (1451–1506) arrived in the New World in 1492. The Arawak had a complex and highly ceremonial culture. While they had neither a written language nor an advanced system of counting, the Arawak people had a highly developed culture, including a universal language, a system of ceremonial dances, sculpture, jewelry, weaving, music, and poetry. They grew fruit such as guava, papaya, and pineapple, as well as beans, squash, chilies, and tobacco. They played a ceremonial ball game called *batu*, which, like stickball in many southeastern American Indian nations, was also used as a form of conflict resolution. They were governed by a village-based theocracy and were organized around a three-tiered class structure: Each village had a single *cacique*, or chief; *nitainos*, or noblemen; and *nabo-
rias, or the working class. Villages also had bohiques, who functioned as priests and healers.

Taino culture was integral to the development of the postcontact region. Taino place names are still used in many areas (such as the Puerto Rican towns of Utuado and Mayaguez). The Taino also introduced to Europeans the hamaca, or hammock; and the barbacoa, or barbecue; the musical instrument maracas, and a way of making cassava bread. Tainos named the yuca among other plants and the iguana as well as other animals.

Mostly agricultural, seafaring, and peaceful, the Taino had been engaged in a series of conflicts with the more aggressive Caribs for about one hundred years prior to European contact. The Europeans probably confused the Taino with the Caribs and considered them a threat, subject to the Spanish Crown and liable to forced conversion to Catholicism. There is always considerable debate over the size of precontact indigenous populations and the degree to which those populations were reduced by Europeans. When the Spanish arrived on Puerto Rico (or Boriken) in 1508, it is estimated that there were between 20,000 and 50,000 Tainos. The vicious combination of disease, flight, and the wages of an unsuccessful rebellion in 1511 reduced that number to about 4,000 by 1515.

As with many other indigenous people of the Americas, these numbers allowed Europeans to assume that all Tainos had been decimated and no longer existed, although there was and is debate over whether “absorption” or “extermination” is the cause. However, there is no evidence that the Taino were eradicated. Many contemporary Puerto Ricans claim Taino heritage. The Taino are now asking for official recognition as indigenous and sovereign peoples from the government of Puerto Rico and have formed at least two organizations: the United Confederation of Taíno People and the Jatibonicu Taino Tribal Nation of Boriken. There is also a growing movement of Taino revivalism, connected to a broader movement for indigenous resurgence across the Caribbean. Members of the movement advocate cultural preservation and promotion, correction of historical misconceptions, the preservation and maintenance of sacred sites, and environmental protection.

TALENT
The social sciences can have an enormous impact on society by identifying talented individuals and finding methods to fulfill the potentials implied by that talent. Talent generally refers to particular potentials. It can be contrasted with the general ability estimated with tests of intelligence (IQ). Talent is both domain and culture specific.

Exceptional talents have been studied for many years. In his seminal study titled Hereditary Genius (1869), Sir Francis Galton presented data suggesting that talent is inborn. He concluded that talent ran in families, the implication being that there was not much that could be done if an individual was not born into the right family. Galton’s data were derived from archival sources, which did indeed show that the more closely family members were related (e.g., sons and fathers versus cousins), the more likely they would share the same level of ability. The data were biased, however, in that only certain fields were represented. Also, gender bias, common in Galton’s time, meant that only certain careers were open to women and only certain skills were developed in girls. Indeed, educational advantages were at that point given almost entirely to boys and men. The conclusion about heredity seems to have been unwarranted as well. This is because both nature and nurture run in families. Just because talent runs in families does not mean that it is genetically based. Certain experiences are also more common in some families than others. Socioeconomic status, for instance, shows continuity across generations, and this means that certain families will have educational advantages in every generation, while other families will not. In short, talent might appear to be inherited because it runs in families, but that can just as easily be explained in terms of experiences (e.g., educational) that are common to certain families.

It is most realistic to recognize both nature and nurture as influences on talents. Certain biological givens, for example, characterize the entire human race. There is also some indication that the human nervous system has spe-
Talibans for different talents and that these might vary from person to person. Recent evidence suggests that certain talents are tied to particular genes and alleles, such as the dopamine receptor DRD2. Biological influences on talent determine what potentials any one individual will have. Everyone has potentials, but clearly the range of potentials varies dramatically from person to person. If these potentials are recognized, perhaps as a kind of precociousness or giftedness, they may be reinforced and fulfilled through formal and informal educational experiences.

Some talents may require more reinforcement (and more experience) than others. Musical talent, for example, is apparent very early in life, in part because the individual need not master a huge corpus of information. Mathematical talent is not apparent quite as early, but still is manifest by approximately age ten. Other fields may require the individual to master a large knowledge base, and for that reason more experience is necessary. Talent in an area such as physics, then, would not be fulfilled until adulthood.

Although talent often develops to the degree that it is valued and reinforced, sometimes the causality is the other way around and the talent has an impact on the experiences obtained. This occurs when parents or teachers recognize a child’s potential and react to it by providing optimal experiences. Talent is not, then, entirely dependent on nurturance; it can also determine what experiences are most likely to occur. In short, talent and experience have a bidirectional causal relationship.

One of the most influential theories of talent was presented by Howard Gardner (1983). Often called the theory of multiple intelligences, his view distinguishes eight domains of talent: verbal-symbolic, mathematical-logical, musical, spatial, bodily-kinesthetic, interpersonal, intrapersonal, and naturalistic. Gardner’s theory is widely recognized in part because it is based on data from experimental, psychometric, cognitive, biographical, and developmental investigations, and in part because it avoids common cultural biases. In Western culture, for example, the emphasis is on verbal-symbolic and mathematical-logical talents. These are emphasized in the schools much more than the other domains. But other cultures (and eras) emphasize other talents.

Even within one culture, views of talent vary with the passage of time. Athletic skills such as hitting or catching a ball, for example, were probably not greatly valued in the early part of American history, though now these skills can lead to scholarships and lucrative careers. What may be most important is the implication that some talents are presently not recognized. This further implies that there are human potentials that are not being fulfilled. Some of these may be extremely important for world peace and the preservation of the environment.

Talent is probably best identified and nurtured by looking beyond cognitive ability. Certainly cognitive ability plays a role, but there is much more to it. A potential talent will not even be fulfilled unless the individual invests time in the domain in question. Joseph Renzulli recognized cognitive and extracognitive aspects of exceptionally. Here, general ability plays a role, as does creative potential and task commitment. The last of these reflects interest, motivation, and persistence. Clearly educators should look for each of these contributions to talent (general ability, creative ability, and motivation).

The domain-specific view of talent is also useful in the educational setting. If educators recognize a variety of different talents, the potentials of each child can be fulfilled. Instead of identifying as gifted only children who are exceptional in verbal or mathematical skills, each individual’s talents can be reinforced.

TALIBAN
The Taliban is a radically militant Islamic movement that controlled some 90 percent of Afghanistan between 1996 and 2001. The Taliban emerged from their base in Kandahar in southwestern Afghanistan in reaction to the lawlessness caused by infighting between rival mujahideen forces in the wake of the Soviet withdrawal in 1989. The Taliban’s declared aims included the restoration of peace, rigid enforcement of Islamic law, disarming the population, and defending the Islamic character of Afghanistan.

In 1994 the Taliban, under the leadership of Mullah Mohammed Omar, began its territorial conquest with the seizure of the Afghan border post of Spin Boldak and subsequent takeover of the city of Kandahar. The fall of Kandahar provided the Taliban with a nucleus of fighters as thousands of Afghan refugees, mostly students at madrassas (Islamic religion schools) near the Afghan-Pakistani border, joined the movement. The Taliban’s swift military successes launched a surprising advance that culminated in the capture of the Afghan capital, Kabul, in 1996.
The Taliban set out to create the world's most pure Islamic regime by introducing a disturbing and deeply revolutionary form of Muslim culture that came at a tremendous cost to human freedom. Men were ordered to keep their beards to a specific length, and subjected to punishment for defiance. Members of minority groups were labeled to distinguish them as non-Muslims, a measure the Taliban argued was to protect them from religious police enforcing Islamic law. Frivolities such as television, the Internet, music, and photography were outlawed. Punishments including amputation of the hands of thieves and the stoning to death of women convicted of adultery, considered severe by European standards, were common under the Taliban.

It was the Taliban's anti-woman agenda, however, that caused mounting concern around the world. Under the Taliban women were forbidden to work outside the home, were compelled to wear a head-to-toe covering known as a burka, and could not leave the home without a male guardian. Such issues, along with restrictions on women's access to health and education, caused resentment among ordinary Afghans and drew the ire of the international community. To the Taliban, however, the restrictions served to preserve the honor and dignity of women who had previously been preyed upon.

Despite their strict beliefs and anti-drug profile, the Taliban could not resist using opium to fund its activities, underlining the movement's poor understanding and interpretation of Islamic law. Though the Taliban leaders led an austere life in contrast to the ostentatious lifestyle of the mujahideen warlords, their economic policy was left in the hands of chance and fate, culminating in Afghanistan's slide into economic backwardness.

Only three countries, the United Arab Emirates, Pakistan, and Saudi Arabia, established diplomatic ties with the Taliban government. Both Pakistan and Saudi Arabia distinguished themselves among foreign powers by the scale of their efforts and support for the regime. Although it is officially denied, there is widespread agreement that the Taliban gained crucial early support from the Pakistani army and intelligence services, especially in helping make the Taliban a highly effective military force. Pakistan, influenced by its geopolitical and economic interests, remained a strong diplomatic and economic lifeline for the regime.

In Saudi Arabia the Taliban's push for a pristine Islamic society was in accord with the Saudi's strict form of Wahhabi theology and law. Saudi Arabia bankrolled the madrassas in Pakistan that provided an ideological guide for the Taliban. A great deal of uncertainty remains about the extent of Saudi Arabia's assistance to the Taliban but the consensus appears to be that their aid was largely financial.

The Taliban enjoyed a cozy relationship with Al-Qaeda and found in the group a useful ally, especially in the significant boost Al-Qaeda provided to the Taliban's military campaigns against the Northern Alliance. Al-Qaeda enjoyed a comfortable refuge in Afghanistan under the Taliban regime.

The Taliban made giant strides in uniting the country but ultimately was unable to end the civil war. The strongest opposition to the Taliban came from the Northern Alliance, who controlled the northeast region of Afghanistan. This group backed the U.S.-led coalition that ousted the Taliban from power in 2001.

TALLY’S CORNER
Tally’s Corner: A Study of Negro Streetcorner Men (1967), by the American anthropologist Elliot Liebow (1925–1994), represented a breakthrough for its time in studies dealing with poverty and race. Tally’s Corner was originally written as Liebow’s PhD dissertation in anthropology for the Catholic University of America.

For twelve months in 1962 and 1963, Liebow and a group of researchers studied the behavior of a group of young black men who lived near and frequently hung around a street corner in a poor black neighborhood in downtown Washington, D.C. Liebow’s participant observation revealed the numerous obstacles facing black men on a day-to-day basis, including the structural and individual levels of racial discrimination propagated by whites in society.

Liebow’s observations about young black men in the ghetto, a complex system comprised of an overabundance of liquor stores, pool halls, and pawnshops, directly parallel similar research by notable scholars, such as William Foote Whyte (1914–2000) in Street Corner Society (1943). In this respect, Tally’s Corner represents one of the first ethnographic attempts at understanding how groups nav-
igate extreme poverty in the inner cities. The book shares some similarities with W. E. B. Du Bois’s (1868–1963) *The Philadelphia Negro* (1899) in that throughout *Tally’s Corner*, Liebow elaborates on the cultural deficiencies of blacks in the ghetto and is quick to attribute these deficiencies as the root cause of their perpetual poverty. Unlike Du Bois, however, Liebow fails to factor in the effects of racial discrimination against blacks in the employment sector and in access to quality education and how these structural elements affect the lives of black people living in the ghetto.

Nevertheless, *Tally’s Corner* is unique in how it looks at not only poverty and its effects on inner-city people but specifically on the systemic and long-term effects of poverty on black men and black families. In the five main chapters that make up *Tally’s Corner*, Liebow discusses how black men deal, on a daily basis, with issues of work, their relationships, their children, and their friends and networks. His portrait of how inner-city blacks navigate the racial waters of their neighborhoods is both gloomy and sad, revealing a number of examples of how whites are apathetic and often discriminatory toward black workers. Black men’s constant struggle to succeed and their frequent failures translate for Liebow into a self-perpetuating cycle of doubt, where blacks become tired of trying to beat white society at its own game and thus accept failure as a way of life.

The sociologist and ethnographer Elijah Anderson, following Liebow’s tradition of urban ethnographic research into black lives in the inner city, has spent a lifetime studying race and class issues in urban communities. An explicit example of the continuity of Liebow’s work is in Anderson’s *Code of the Street* (1999), an ethnographic study examining morality, teen pregnancy, the search for respect, and other issues central to people living in the inner city.

Although Liebow’s study offers valuable insight into the lives of young and poor black men in the early 1960s, his analysis caters to what the psychologist William Ryan (1923–2002) labeled a “blaming-the-victim” mentality or what the anthropologist Oscar Lewis (1914–1970) referred to as a “culture of poverty,” whereby the structural inequalities in society are not questioned. Rather, blame for persistent social ills is placed directly onto the victims themselves. A clear example of the use of a blaming-the-victim argument is in the 1965 Moynihan Report, which argued that unemployment and a lack of educational success among black Americans could be traced to dysfunctional black families. Hence the burden of misfortune is shifted directly onto black Americans.

In a similar vein, Liebow argued that the relentless patterns of racial discrimination by whites had left black men with low self-esteem and thus a desire to remain une-duced and unattached to their children or families. The problem with this argument is that it fails to account for the real and pervasive racial dilemmas faced by blacks in the United States. For example, Liebow argued that as long as black Americans failed to become educated, they would remain ignorant of the opportunities provided many whites. Thus education is a key, for Liebow, in lifting black men out of poverty. However, what is left out of Liebow’s equation is that the racial discrimination that occurs in the school system is real and that for blacks education may not necessarily equal opportunities for success. As Joe Feagin, Amanda Lewis, Judith Blau, and many other researchers have noted, the American education system is a racialized institution that fundamentally caters to middle-class whites while routinely denying blacks and other nonwhites equal opportunities for learning and advancement. Likewise, Liebow ignores the impact of racial discrimination in employment as a major factor affecting blacks’ opportunities for upward social and economic mobility. Thus for blacks living in the ghetto, the racial structure of society is such that even should they succeed in navigating the educational obstacle course, they will continue to suffer penalties in rewards vis-à-vis comparably educated whites. This fact not only affects the social and economic mobility of black Americans, it also has an adverse impact on the motivation of blacks living in the ghetto to follow through on their education.

Numerous studies have criticized *Tally’s Corner* for its failure to consider the impact of institutional and systemic racism on the lives of blacks in the United States. For example, Steven Gregory’s *Black Corona* (1998) argues against the idea that the black ghetto is dysfunctional and socially disorganized. Rather, like Kenneth B. Clark (1914–2005) in *Dark Ghetto* (1965), Gregory maintains that the black community has been rendered powerless by urban political processes, even as black Americans continue to organize and fight for social justice. A more direct critique of *Tally’s Corner* is in James Borchert’s *Alley Life in Washington* (1980). Borchert finds order and stability in his examination of alley housing in Washington, D.C., and he directly rejects the view of lower-class black life as pathological.

**BIBLIOGRAPHY**

Tariffs are discriminatory taxes collected at the border on imported goods but not levied on similar goods originating domestically. Tariffs are sometimes very large (everywhere in the 1930s and in some developing countries in the early twenty-first century) and sometimes very low (Hong Kong in the early twenty-first century). Tariffs are substantially discriminatory between international trading partners. Regional trade agreements such as the European Union (EU) and the North American Free Trade Agreement (NAFTA) remove tariffs between the members while imposing tariffs on nonmembers. Tariffs also significantly discriminate between goods. Tariff schedules of most countries contain over 10,000 lines with tariffs ranging in some cases from 0 percent to over 100 percent.

Tariffs come in specific and ad valorem forms. Specific tariffs are charges per unit, for example, $1,000 per automobile. Ad valorem tariffs are levied as a percentage of invoice value. A 5 percent tariff levied on a $20,000 automobile yields a $1,000 specific tariff equivalent. The automobile example also illustrates how to calculate the ad valorem equivalent of a specific tariff: divide the specific tariff by the invoice price. Ad valorem tariffs are much easier to use for comparison purposes across goods and countries. Comparison including specific tariffs requires prices to deflate the specific duties, which is often extremely burdensome.

Both specific and ad valorem tariffs are common. Ad valorem tariffs are the only sensible type when there is no natural quantity unit (boxes of parts). But ad valorem tariffs are disadvantageous where corrupt border officials are suspected; under invoicing will lower the tax paid, with importer and border official splitting the difference. History also matters: The United States has many specific tariffs despite the likely honesty of its customs officials.

Some tariffs vary with the level of trade. The tariff quota is a tariff that steps upward when trade passes a preset amount. Another example is an antidumping duty, which is equal to the difference between last year’s price differential between the exporting firm’s cost (or foreign price) and its U.S. sale price.

TARIFF COSTS AND BENEFITS

Tariffs provide revenue to the government that levies them. This benefit is offset by the cost to users of paying the tax. Less obviously tariffs provide a benefit to domestic producers who experience less stringent competition from imports. The balance of these three effects is typically calculated to yield a net loss to the economy. A tariff reduction is typically calculated to reduce net loss by the height of the tariff times the increase in imports induced by the tariff reduction. The marginal net cost of tariffs is thus proportional to the height of the tariff.

A potentially important complication is that import competition may cause periods of unemployment for domestic workers; hence, tariffs provide a benefit by employing more workers. Typical calculations for the U.S. economy show that the costs of employment-increasing tariff hikes per job saved are greater than the wage paid in the job—usually several times the wage.

What explains the use of tariffs in view of their cost to the economy? Politics. The pressure of domestic producers and trade unions that gain from tariffs is largely unopposed. Consumers are unorganized whereas producers who import intermediate goods often refrain from resisting tariffs as they push for tariffs on the import of goods that compete with their output. Two contrary forces push tariffs down. Most importantly, politicians tempted to grant higher tariffs also know that the resulting reduction in general prosperity harms their prospects of retaining power (at the next election or, less certainly, against a coup). More subtly, the interest groups themselves bear a share of the overall cost of tariffs, tending to restrain their demands. Political economy models that view tariffs as objects for sale in political markets with
these forces at work have been fitted to data on the pattern of protection, and the model appears to statistically explain the pattern well.

The discriminatory aspect of tariffs (differing across trading partners and across goods) typically adds to the cost of tariffs. Discrimination across trading partners results in costly trade diversion. The purchase of goods shifts from the lowest cost source (increasing net loss in proportion to the tariff if the source is not a partner) to the favored partner (with marginal net benefit equal to the zero tariff). Discrimination across goods imposes a more subtle cost on the economy with a similar structure. Think about increasing the dispersion of tariffs while preserving the average tariff. The increase in tariffs on already high-tariff goods reduces trade where it is most costly whereas the reduction in tariffs on low-tariff goods increases trade where it is least costly.

Discrimination across trading partners and across goods is substantial and has increased with the overall liberalization of trade since the mid-1900s. Regional trade agreements have proliferated even as multilateral negotiations have reduced overall tariffs. Wide tariff reductions have exempted certain product categories, such as agriculture and apparel, in rich countries.

### INTERNATIONAL TRADE RELATIONS

Tariffs tend to reduce prices of exports from foreign economies. This spillover implies that part of the cost of tariffs is borne by foreigners. Since national governments will thus be tempted to overuse tariffs, nations agree to restrict their tariffs in international negotiations and enforce their agreements through international institutions such as the World Trade Organization (WTO). The dispute settlement process of the WTO generates frequent headlines and gives a false impression that international relations are becoming more acrimonious. As with family therapy, if the parties are arguing, it is better than if they are not talking. Imperfections in particular negotiation rounds or institutions should not obscure their very positive role in preventing much worse outcomes, such as the tariff wars of the 1930s.

Two basic principles of the WTO and its predecessor institutions are nondiscrimination between partners and reciprocity. Reciprocity means that the parties alter their tariffs to balance the exchange of market access provided. For example, a round of tariff negotiations might increase U.S. imports by one trillion dollars while reciprocally increasing access to foreign markets by one trillion dollars. Importantly, the WTO permits the United States to withdraw market access of, say, one billion dollars, by raising its tariffs in a particular product while reciprocally authorizing the foreign countries to withdraw one billion dollars of market access by raising foreign tariffs.

Regional trade agreements are the great exception to nondiscrimination. The principles of the WTO permit it on the reasoning that a move toward free trade between the members is better than the move away from liberal trade due to trade diversion. Opinions among trade economists diverge over whether regional agreements are a building block or a stumbling block to multilateral liberalization.

### TASTES

It is telling that economists use a term reserved for one of the five senses, *taste*, to denote human desires and motives. This indicates first that economists consider human desires as private and therefore not subject to moral valuation. One cannot be scolded for having taste buds that prefer sour cream, for example, to yogurt. Similarly one cannot be scolded for liking pushpin (a triviality, a children’s game) better than poetry—the examples used by the founders of utilitarianism, Jeremy Bentham (1748–1832) and John Stuart Mill (1806–1873). Second, this signifies that economists consider human desires as personal and therefore not subject to interpersonal utility comparison. As much as it is supposedly impossible to compare A’s taste buds for sour cream with B’s, one cannot compare A’s utility from consuming an extra automobile with B’s. Third, this suggests that economists consider
desires as fixed and therefore not to be tampered with to explain behavioral puzzles.

Whether neuroscientists regard the taste buds as private, personal, or fixed is another matter. At issue is the accuracy of the economists’ assumption of tastes as private, personal, and fixed. It is easy to see the limits of each of these assumptions, as many social scientists have shown. Nonetheless, they persist in mainstream welfare analysis and in economics textbooks. They have proved impervious to criticism because they lend themselves easily to the thrust of economic analysis. Namely, it is about rationality: how agents respond to incentives so they can maximize a given end by a given set of means (Robbins 1935).

Economists have identified several axioms as the necessary conditions of rationality. The most important are two axioms concerning how agents compare alternative bundles of goods according to their own tastes; that is, how tastes become “preferences.” According to the transitivity axiom, the preferences must be consistent. If an agent prefers A to B and B to C, then he or she must prefer A to C. According to the completeness axiom, the agent must be complete with his or her tastes. He or she must know how to rank all the bundles within his or her feasible set. This allows the agent to be decisive.

Empirical and experimental findings by behavioral-decision researchers in psychology and behavioral economists have questioned the axiom of transitivity. For instance, how one values a product may change depending on whether or not one owns the product, called the “endowment effect” (Thaler 1980) or “loss aversion” (Tversky and Kahneman 1991). It seems that agents value something more if they happen to own the item; the price at which they are willing to sell the item is higher than the price they are willing to pay for it. Some researchers have questioned this endowment effect on different grounds (Shogren, Shin, Hayes, and Kliebenstein 1994; Hanemann 1991; List 2001). Concerning the axiom of completeness, the parable of Buridan’s ass illustrates the problem of indecision. Agents may simply fail to rank two equally appealing bundles (Khalil 1997).

Economists are still in disagreement about how to interpret the empirical and experimental findings that question these axioms. This short entry tackles the assumptions about tastes from another angle: by directly examining the assumptions that tastes are private, personal, and fixed.

TASTES AS PRIVATE
The assumption that tastes are private allows economists to treat all tastes—such as pushpin, cockfight, Aristotle’s Politics, altruism, and poetry—as fungible. This allows economists to place them as elements in a single utility function. In this manner, an agent would buy more poetry if the price of cockfight tickets increased. If an agent holds irreconcilable utility functions, as the multiple-self approach maintains (Elster 1986), the agent’s ability to economize across all tastes will be compromised.

The treatment of tastes as private comes at a price. It means that there is no room for educators and public figures to try to upgrade the tastes of the citizens. The upgrade would be deemed as arrogant and constitute interference in the citizens’ private lives.

However, this may not be necessarily the case. It is possible to maintain the fungibility of tastes, and hence allow for the calculus of optimization to proceed, without the tastes-as-private assumption. That is, it is possible to recognize a qualitative difference between pushpin and poetry without undermining utilitarianism or the idea of a single utility function. For instance, John Harsanyi (1997) and Yew-Kwang Ng (1999, 2003) distinguish between actual preferences, on the one hand, and informed preferences, on the other. Ng identifies ignorance as one reason, out of several others, that agents would fail to choose the more welfare-enhancing, informed preferences. For Ng, agents would want informed preferences in place of actual ones because the informed preferences would afford happiness. Also one can argue that agents, with sufficient practice and education, would find no discontinuity between coarse entertainment and high-culture entertainment.

TASTES AS PERSONAL
The assumption of tastes as personal permits economists to avoid thorny political issues concerning the distribution of income. Economists usually restrict themselves to policies that avoid interpersonal utility comparison, based on what is known as the Pareto welfare criterion. This criterion stipulates that a policy maker can reallocate resources as long as it makes at least one agent better off without reducing the welfare of anyone else.

However, as Adam Smith (1723–1790) amply shows in The Theory of Moral Sentiments (1759), humans have the capacity to place themselves in the shoes of others, a quality he called sympathy. Sympathy, which can be extended to nonhuman animals, is a method of interpersonal utility comparison. It allows the agent to judge whether the pleas of others are justifiable, given the costs involved (see Khalil 2006).

TASTES AS FIXED
The assumption of tastes as fixed involves two separate flavors: first, fixity of tastes across agents or cultures; second, fixity of tastes across time for the same agent.
Fixity across Agents or Cultures The fixity of tastes across agents or cultures allows economists to explain differences in behavior solely on the basis of differences in income and relative prices. This prevents scientists from inventing tastes in an arbitrary fashion. For George Stigler and Gary Becker (1977), to explain differences in behavior in terms of differences in taste amounts to an intellectual retreat. For instance, cohabitation in place of marriage in the United States and western Europe is currently free from stigma. In many other cultures, and in the historical past of Euro-American culture, cohabitation amounts to living in sin. It has been punished by ostracism or even death, known as honor killing. To explain the disappearance of the stigma surrounding cohabitation, it would be an intellectual retreat to state: “Oh, Europeans and North Americans are now humane; they shed the backward values.” Also if we see Agent Z suddenly buying more oranges than usual, it would be an intellectual retreat to hypothesize: “Oh, Agent Z suddenly started to like oranges more.” Such answers are intellectually unsatisfying because they beg certain questions: Why did the rest of the people in the world not become as enlightened as the North Americans and the Europeans? Why did Agent Z change his or her taste?

It is a better strategy to assume that tastes are stable, that is, the same tastes prevail across cultures and agents and to examine instead changes in incentives. Concerning cohabitation, there are several candidates: the introduction of the contraceptive pill in 1964, the spread of the welfare state, and an increased division of labor that facilitates female participation in the workforce. Each of these factors lowers the risk or cost of pregnancy and therefore lowers the cost of cohabitation relative to marriage. Also, concerning oranges, there are several candidates: lower prices of oranges, higher prices of all other fruits, or new information about the health benefits of oranges, for example. All of these candidates deal with the change of constraints and therefore avoid the intellectual retreat.

It would also be an intellectual retreat to evaluate the economic performance among countries by appealing to differences in cultural tastes (Khalil 2007a). If we witness one economy performing better than another, it would be an arbitrary assumption to suppose that the people of the better-performing economy had different tastes from the other. A more challenging task is to look for differences in climate, endowment, or relative prices. In fact it is crucial for analysis to maintain the fixity of tastes across cultures. Of course cultures have different tastes for how to prepare coffee or what to eat for breakfast. But such differences are trivial in comparison to fundamental issues, such as investment, innovation, and entrepreneurship. These issues are of universal concern for human survival. Given this, it is important to resist the rising tide of culturalist economics that tries to explain the debacles of, for example, Latin America or Islam in terms of fundamental cultural values (North 2005).

In the same vein, if one sees a person indulging in gambling or alcohol to the point of dysfunction, one should not invent new tastes, such as the theory that some people have a weak will toward present consumption while others have a strong will. This would be an intellectual retreat (Khalil 2007b). To see how or why some agents become addicted to or indulge in reckless activity, it is more intellectually appropriate to assume first that agents have the same tastes. Of course agents have different tastes, but such differences should be accounted for endogenously rather than as the entry point of analysis. This is especially the case if one intends to analyze actions that lead to the dysfunction of the agent, broadly called weakness of will, such as addiction and recklessness. It is important, then, to resist the rising tide of behavioral economics that tries to explain weakness of will as simply the result of present-bias tastes, which amounts to quasi-hyperbolic discounting (Laibson 1997; O’Donoghue and Rabin 1999).

Also the behaviorist onslaught has created new tastes, aside from the ones to explain weakness of will. It has created tastes for envy, jealousy, fairness, social preferences, and so on (Gintis, Bowles, Boyd, and Fehr 2005). In this manner, behavioral puzzles are not interrogated in relation to welfare or well-being (Khalil 2000, 2004). Rather, the puzzles are “solved” by the question-begging invention of new tastes. In fact economists are not short of evolutionary stories about the stability of populations with such new tastes (Francois and Zabojnik 2005; Gintis 2003a; Gintis 2003b; Bowles 2004, chap. 2). Such stories fundamentally depend on the variability of lineages of tastes across agents—true to the neo-Darwinian assumption of diverse lineages in the population as the prerequisite of natural selection. Such evolutionary stories then proceed to show why a lineage, such as a social preference toward trustworthiness, can become dominant. Namely, the lineage becomes dominant if it already exists in the population above a critical frequency. But such evolutionary stories amount to establishing the stability of the new taste at hand. They do not provide an endogenous account of the origin of the lineage. Worse, it is unlikely that members of a population would simultaneously experience a mutation of the same kind at a scale that is required to reach a critical mass.

Fixity across Time The fixity of tastes across time for the same agent, which can be called the “economics Archimedean rock,” affords the celebrated assumption of consumer sovereignty. This assumption allows economists to undertake a static welfare comparison. If an agent’s tastes are manipulated by powerful entities, such as firms
and their advertising arms (Galbraith 1958) or the culture of competitive markets (Bowles 1998), the result is that the tastes of the consumer are not stable enough over time to afford welfare comparisons. If a monopolist $M$ “brainwashes” or “educates” consumers to love $C$ more if it is in its container $M$ than if it is any other container, $M' - U(CM) > U(CM')$, then consumers suffer when $CM'$ replaces $CM$ as a result of the breakup of the monopoly. Thus researchers cannot capture the welfare benefit, such as lower prices of $C$, as a result of the breakup of the monopoly.

The problem of change of tastes across time is about innate change. The problem, as discussed here, is not about fashion or fad. The issue of fashion deals with a covariation of tastes across consumers that is not prompted by a change of income, relative prices, or the innate change of taste. The change of tastes due to fashion, as Edi Karni and David Schmeidler (1990) suggest, does not threaten the idea of fixed tastes. They trace the phenomenon of fashion to the social aspect of the consumption of the goods under question, which explains the cyclical behavior.

The problem of change of tastes across time discussed here is, rather, due to the development of the agent, which is usually path dependent, where habits play a supreme role. Gary Becker (1996, chap. 1) proposes the notion of personal capital that is augmented through consumption. Past consumption enhances the marginal utility of current consumption, which becomes the basis of habit formation. Becker argues that the endogenous change of tastes across time does not result in unstable tastes. While the subutility function changes as a result of habit formation, the extended utility function is stable. Given the stability of the extended utility function, consumer sovereignty is preserved, so static welfare comparison is possible. Along a different vein, Ng (2003) uses the analysis of happiness, based on informed and nondeceiving preferences, to help researchers to judge welfare when there is a change of tastes.

Robert Sugden (2004) also deals with consumer sovereignty in the face of changing tastes. For Sugden, however, tastes change because they are reference dependent, where the reference can be the endowment (endowment effect) or the present (weakness of will). Given that tastes change with arbitrary factors, such as endowment or temptations afforded by the present, tastes amount to incoherent preferences. The normative economics Archimedean rock cannot be the satisfaction of preferences. Sugden suggests that consumer welfare should be evaluated according to the opportunity or freedom that the consumer has to assert his or her right to take care of himself or herself. Welfare therefore is not primarily about preference satisfaction. It is primarily about the freedom to pursue one’s preferences, which can be incoherent. Such freedom, possessed by the individual, should be the true meaning of “consumer sovereignty.”

CONCLUSION
Economics would greatly benefit from dropping the assumptions that tastes are private, personal, and fixed across time for the same individual. The only assumption about tastes that, at first approximation, is worth preserving is the fixity of tastes across agents or cultures. This should not mean that, at second and tertiary approximations, cultures and agents have identical tastes. However, for fundamental issues—such as weakness of will, trustworthiness, entrepreneurship, and cohabitation—it is imperative not to explain differences in practice in terms of differences in taste. Such an explanation would be an intellectual retreat.

Tâtonnement

Elias L. Khalil

**Tâtonnement**

*Tâtonnement*, a concept introduced by French economist Léon Walras (1834–1910), is a trial-and-error process by which equilibrium prices and stability are reached in competitive markets. Walras found that “the markets which are best organized from the competitive standpoint are those in which purchases and sales are made by auction” (Walras 1954, pp. 83–84).

In an auction market, the *tâtonnement* process starts when the price is fixed (called out), and then demand and supply states are revealed. One possibility is that demand and supply conditions are balanced, establishing normal prices. The most likely state is disequilibrium, where the market will show excess supply or demand, causing deviation of the actual from the natural price. If equilibrium prices are not obtained, then *tâtonnement* requires the auctioneer to increase or lower prices, depending on the demand or supply conditions. In this groping process, the market mechanism would make the actual price gravitate to its natural level, establishing equilibrium. As long as equilibrium is not achieved, no contracts for selling or buying will be executed. The modern literature has conferred the name *nontâtonnement* on the situation where trading does take place at false prices. An unsolved problem with the *tâtonnement* process is whether to make it compatible with the solutions of equation systems by counting equations and unknowns as Walras did, or through more complex general equilibrium solutions such as fixed-point methods.

Walras’s analysis of the *tâtonnement* process was challenging because both equilibrium levels and stability conditions were required. Walras compared the stability analysis to a pendulum-like mechanism in which “the center of gravity lies directly beneath the point of suspension, so that if this center of gravity were displaced from the vertical line beneath the point of suspension, it would automatically return” (1954, pp. 109–112). That concept of stability remains in vogue. John Hicks’s (1904–1989) research (1946) was an early attempt to make Walras’s arguments transparent to economists. With two commodities, *X* and *Y*, Hicks explained that equilibrium required that the supply of *X* be equal to the demand for...
X. Stability requires that a fall in the relative price of X to Y, which will make X cheaper, will increase the demand for X above its supply. For multiple commodities, Hicks realized that when the relative price of X to a standard commodity changed, we need to know what will happen to the prices of the other commodities, which can be assumed fixed, or assumed to move to their equilibrium levels. The classical economist Alfred Marshall (1842–1924) simplified this with his introduction of ceteris paribus assumption, which held changes in all other prices constant.

Paul Samuelson improved the process by making Hicks’s contribution more dynamic. For a one-commodity case, Samuelson (1941, p. 102) wrote a price differential equation of the form \( \frac{dp}{dt} = H(q_d - q) \), where the rate of change in prices, \( dp \), with respect to changes in time, \( dt \), is a proportion, \( H \), to the difference between demand and supply, \( q_d - q \). This model addresses multiple markets by allowing the demand and supply variables to depend on the prices of say \( n \) commodities, \( p_1, \ldots, p_n \). In the commodities case, the model implies that if we plot excess demand for good 1 against the relative prices, \( p_1/p_2 \), we obtain solutions for the prices when the excess demand function crosses the relative price axis. Stable conditions are obtained only when the excess demand cuts the relative price axis from above, implying that the excess demand function is downward. Stability is obtained because if the actual price ratio is higher than the equilibrium price ratio, then excess supply of good 1, and excess demand for good 2, are obtained, and prices will adjust accordingly so that the actual price ratio goes back to equilibrium.

For more than two goods, the Samuelsonian development of the \( \text{tâtonnement} \) process cannot be generalized. While Samuelson improved upon Hicks’s model in the dynamic realm, his correspondence principle shows that static and dynamic relations are both useful concepts. Samuelson (1960, p. 368) also developed the Le Chateliers principle to explain adjustment to equilibrium after an initial displacement. Increases in demand will cause the relative price, say, of goods \( H_u \) to increase. If the prices of the other goods, \( H_{u-j} \), increase, then it will lower the increase in the price of \( H_u \). The increased price of \( H_u \) will be smaller if the price of \( H_{u-j} \) is also unchanged. The metaphor for this process is that squeezing a balloon will decrease its volume more with constant temperature than if we let its temperature warm up during the squeezing.

As Franklin Fisher (2006, pp. 143–144) pointed out, this treatment represents the \( \text{tâtonnement} \) process when only prices adjust and trade does not take place at disequilibrium prices. The solution is, therefore, unsatisfactory, because many prices are fixed and auctioneers are not present in all markets.

TAWNEY, R. H.  1880–1962

Richard Henry Tawney, teacher, social scientist, journalist, and political moralist, was born in Calcutta in 1880. Of upper-middle-class origin, Tawney was sent to Rugby School in England, where he developed something of the moral thoughtfulness for which Thomas Arnold (1795–1842) had made that institution famous. After Oxford University, where he attached himself to reform-minded circles, and social work at Toynbee Hall, a settlement house in London, Tawney found his vocation in education. He spent most of his career at the London School of Economics and Political Science and was also pedagogically and administratively active in the adult education movement. An English patriot, Tawney served in both world wars. His childless marriage to Annette Jeanie Beveridge, sister of a prominent Liberal politician, lasted...

Tawney’s discipline was history, specifically economic history, a field that he helped to establish. He produced several scholarly monographs, including Religion and the Rise of Capitalism (1926), a study of religious social thought of the sixteenth and seventeenth centuries and its relationship with emergent economic forces. In a celebrated footnote, Tawney questioned Max Weber’s (1864–1920) thesis of a simple causal relationship between a homogeneous Protestantism and the growth of entrepreneurialism, suggesting instead that the capitalist spirit, as well as being of older vintage, had additional, nonreligious influences. While its arguments and strongly didactic style were themselves controversial, Religion and the Rise of Capitalism became a minor classic that has been translated into at least seven languages.

However, it was in a nonprofessional capacity that Tawney made his greatest mark. He became an important theoretician of the democratic Left, guiding the philosophy and tactics of the Labour Party through books, articles, policy documents, and editorials (principally for the Manchester Guardian) as well as by an irreproachable personal example. Two works were outstanding in this regard. The Acquisitive Society (1920) challenged the individualism and greed that Tawney associated with the system of industrial capitalism, proposing in its place a society based on principles of cooperation, professionalism, and service. His most important political volume was Equality, first published in 1931 and updated in 1938 and 1952. Here Tawney indicted the maldistribution of resources in Britain and set out a strategy for equality comprising progressive taxation, extensive public ownership, and a generous welfare state.

Another key text is Tawney’s private diary of 1912 to 1914. Unencumbered by the elaborate, irony-laden erudition of his published writings, Tawney’s Commonplace Book (published posthumously in 1972) contains in brilliant aphoristic outline the germ of his mature social philosophy. In particular, it reveals that Tawney’s political idealism was securely anchored in profound Christian convictions. The final entry, for example, identifies an urgent imperative “to make society, when it is at peace, a field in which mere power, ruthlessness, [and] ambition, cannot override the merciful and gentle” (p. 83).

Elements of Tawney’s approach have been overtaken by such postindustrial trends as the decline of manufacturing (at least in the developed world) and the coming of a global information society. Nevertheless, the essence of his position—an ethically grounded, scrupulously honest argument for a free, fair, and fraternal society—has remained persuasive to many sections of the moderate Left in Britain, the United States, and elsewhere. The passing of time thus confirms Tawney’s central place in the canon of democratic socialism.

TAX BURDEN

SEE Tax Incidence.

TAX CREDITS

A tax credit is an amount that reduces payable taxes during a specific time period. Tax credits occur because a particular expense is tax deductible or because of a public policy that provides a credit up to a fixed amount. In order to calculate a tax credit, we use the following equation: Tax Credit = (Tax deductible expense) * (Tax rate).

In some countries interest expenses, depreciation, labor costs, and raw materials costs are tax deductible from a company’s taxable profits. Hence equivalent tax credits are estimated based on these expenses. Tax credits have a meaning only when a company (or an individual person) has enough profits to be taxed. Specifically in Australia, Canada, the United Kingdom, and the United States, a tax credit is considered a disbursement (payment) toward taxes owed by a company or individual. There is a similar item in the French tax system, though under another name.

A tax credit differs from a tax deduction, tax allowance, or tax relief because the latter three reduce taxable income, whereas the tax credit decreases tax liability unit for unit—in other words, it reduces the tax itself. Tax
credits can be divided into two categories. The first consists of refundable (or non-wastable) tax credits, which can decrease owed taxes below zero and which thus lead to a net payment to the taxpayer, greater than their payments into the tax system. Hence they function like a moderate form of negative income tax. Examples of this type of tax credit in the U.S. tax system are the Earned Income Tax Credit and the Child Tax Credit. In the United Kingdom tax system examples include the Working Tax Credit and the Child Tax Credit. The second category consists of nonrefundable (or wastable) tax credits, which cannot reduce owed taxes below zero and thus do not allow the taxpayer to get a refund in excess of his or her payments into the tax system. Examples of this type of tax credit in the U.S. system include two educational tax credits, the Hope Tax Credit and the Lifetime Learning Tax Credit. Examples in the United Kingdom tax system include the former Children’s Tax Credit and the Declared Gifts Tax Credit, given to registered charities under the Giftaid scheme.

**Tax Credits in the United States**

Principal tax credits in the U.S. tax system include the Child Tax Credit, the Federal Tax Credit for Energy Efficiency, the Earned Income Tax Credit, and the Low Income Housing Tax Credit. The Child Tax Credit (CTC) is based on the number of children in a family. In 2005 an individual could claim $1,000 of CTC per child. According to Internal Revenue Service (IRS) regulations, a child must be claimed as a dependent. To be eligible to be declared as a dependent, a child must have a Social Security number, be related to the taxpayer, be less than seventeen years old, and be a citizen or resident of the United States. The CTC is not available to wealthy people or to those who do not pay any taxes. For a couple (filing a joint return) the maximum adjusted gross income (i.e., combined income) is $110,000. For a single parent it is $75,000, and for a married couple filing separately it is $55,000 each. Finally, it should be noted that if a couple or single parent gets the CTC, this does not prohibit them from getting any other tax credit they qualify for.

The Earned Income Tax Credit (EITC) is a refundable tax credit that decreases or eliminates the taxes paid by low-income people. In some respects it can be considered a wage subsidy for low-income workers. The EITC was established in 1975 and expanded in 1986, 1990, 1993, and 2001. In 2006 this tax credit was one of the major antipoverty tools the U.S. government had and was widely supported.

The EITC has a three-stage structure: the phase-in stage, in which the tax credit increases as earnings increase; the plateau stage, in which the maximum range has been reached and the amount of credit is not affected by an increase in earnings; and the phase-out stage, in which the tax credit decreases as earnings increase. For instance, in 2006 the EITC for a four-member family was equal to 40 percent of the first $10,750 earned, the maximum credit was $4,400, the EITC decreased as earnings passed $15,000, and it became zero when earnings went beyond $35,000.

In 2004 the EITC cost the federal government approximately $36 billion. According to the General Accounting Office and the IRS, 15 to 20 percent of Americans who qualify for the EITC do not claim it. For this reason several nonprofit organizations, with the help of the government, have initiated special programs all over the United States to make the EITC known to taxpayers and to help taxpayers claim it. In addition to the federal EITC, eleven states and some other areas offer local EITC.

Overall the EITC has increased the percentage of people who join the labor force. There is some evidence that this rise in worker supply has caused a decrease in wages (on a per hour basis) for those that qualify for this particular tax credit.

The Federal Tax Credit for Energy Efficiency, which was established by the Energy Policy Act of 2005, applies to people and companies in four categories:

- Consumers who make home improvements to save energy, such as insulation, window replacement, or the installation of heating or cooling systems; or who buy energy-efficient cars, such as hybrid gasoline-electric, diesel, battery-electric, alternative fuel, and fuel cell vehicles, or who install solar water heating, photovoltaic, fuel cell, and microturbine systems.
- Homebuilders who, in order to construct energy-efficient homes, pay for building-envelope improvements and energy-efficient heating and cooling systems.
- Appliance manufacturers who manufacture energy-efficient washing machines, dishwashers, and refrigerators. This in turn can lead to a price reduction for these types of appliances.
- Owners or designers of commercial buildings in which lighting, heating, and cooling systems meet efficiency standards. Credits in this category go up to $1.80 per square foot.

Another category of tax credit is the Low Income Housing Tax Credit (LIHTC), which was established by the Tax Reform Act of 1986 (TRA86). This tax credit aims to give low-income Americans incentives to own a house rather than rent. TRA86 offered incentives to investors to buy homes by changing the treatment of...
imputed rent, local property taxes, and mortgage interest payments. These changes, however, negatively affected low-income people, who usually lived in rented homes. Hence the LIHTC was established along with the TRA86 to mitigate these negative consequences. The LIHTC directly subsidizes the development costs of low-income residential units, excluding land acquisition costs. Tax credits are claimed as an annuity for a period of ten years (the credit period) and not as a lump sum as with other tax credits. Since 2002, 40 to 50 percent of new construction of family residences has been developed under the LIHTC program at a cost to the federal government of approximately $3 billion per year.

**TAX CREDITS IN CANADA**

In the Canadian tax system, one important tax credit is the Canada Child Tax Benefit (CCTB). The CCTB is a monthly tax-free payment available to qualifying Canadian families made in order to help defray some of the costs of raising children. The CCTB can incorporate the National Child Benefit and the Child Disability Benefit. The former is a monthly payment to low-income families with children. The latter is a monthly payment to families with children that have severe and prolonged mental or physical disabilities.

Another tax credit that has existed since 1980 is the Scientific Research and Experimental Development Tax Incentive Program (SR&ED or SRED). This tax credit applies to businesses in Canada and is intended to support and encourage applied research and experimental development leading to new or improved goods and services. The program costs the Canadian government approximately $1.8 billion per year. The Ministry of Finance is responsible for legislation of the SR&ED tax credit, and the Canada Revenue Agency is responsible for its administration.

Even if SR&ED expenses have already been deducted from revenue, businesses may qualify for Investment Tax Credit (ITC) if those expenses are associated with experimental development, applied research, basic research, or research support work. Relevant expenditures include wages, materials, equipment overhead, and SR&ED contracts arising from the aforementioned activities. The amount of the ITC depends on how much of a business’s SR&ED expenses were incurred in Canada and on the business’s legal status. Furthermore each region in Canada has the right to provide provincial or territorial tax credits to qualifying businesses that pursue SR&ED activities in those regions.

**TAX CREDITS IN THE UNITED KINGDOM**

In the United Kingdom tax system significant tax credits include the Working Tax Credit and the Child Tax Credit. To qualify for these credits, a person must be older than sixteen and live in the United Kingdom—either as a British citizen or as a European Economic Area citizen working in the country—or receive a United Kingdom state pension while living abroad. The Child Tax Credit (CTC) is given to people who are responsible for at least one child or qualifying young person. It is paid directly to the person who is responsible for child care. A single parent can claim individually, but a couple must make a joint claim. The Working Tax Credit (WTC) is given to people who are employed or self-employed (either alone or in a partnership) if they meet the following criteria:

- they usually work sixteen or more hours per week;
- they are paid for that work;
- they expect to work for at least four weeks;
- they are older than sixteen and responsible for at least one child, or are sixteen years old and disabled, or are above twenty-five and work at least thirty hours per week on average.

If both people in a couple are working sixteen hours or more per week, only one can receive the WTC. There is, however, also a child care component of the WTC, which is always paid to the person responsible for raising a child, in addition to CTC payments. Before 2003, when the WTC and the CTC were established, the Working Families Tax Credit, created in 1999, combined the functions of the WTC and CTC. Before that, from 1986 to 1999, United Kingdom taxpayers received the Family Credit.

The amount of tax credits received depends on annual income. For instance, a family with income below £58,000 can claim the CTC in addition to child benefits. If a child or children are disabled, higher rates are paid. If the income is below £50,000, the CTC is £545 per year for the family (£1,090 if there is a baby under twelve months old). For low-income families, there is an additional £1,765 per child per year. The CTC can be claimed even by families that are rich. Both the WTC and the CTC are made up of components (elements) according to individual cases that form the basic amount of tax credit receivable. For instance, the basic element is £1,665 for the year 2006–2007, then other elements follow, such as the couple and lone parent element £1,640, the thirty hour element £680, the disabled worker element £2,225, and so on. For the CTC, the family element is £545, and then follow the family element, baby addition £545, the child element £1,765, the disabled child element £2,350, and so forth that are applied according to individual cases. Both these tax credits are paid based on the gross household income earned during the previous tax year.
WTC and CTC tax credits were not well administered when they were first established, and many cases of overpayment were observed. Nevertheless, tax credits are considered an important means of encouraging low-income employees, as they help avoid the disincentive to work that occurs when wages amount to little more than unemployment benefits.

TAX EVASION AND TAX AVOIDANCE

Tax evasion is the use of unlawful means by individuals and firms to reduce their taxes. It refers to taxpayers’ intentional actions that misrepresent or conceal the true state of their financial affairs to tax administrators. An example of tax evasion is taxpayers’ deliberate understatement of their income. Tax fraud is a kind of evasion that involves the falsification of records. In most countries tax evasion is a crime punishable by fines or imprisonment.

Tax avoidance is the use of lawful means by individuals and firms to decrease their taxes. In some countries a distinction is made between tax planning and avoidance. Acceptable tax planning satisfies both the wording and the intent of the tax law. Tax avoidance (abusive tax planning) is consistent with the letter but not the spirit of the law. It usually involves the exploitation of loopholes in tax legislation to the advantage of taxpayers. An example of tax avoidance is transforming highly taxed income into preferentially taxed capital gains. The boundary between tax planning and avoidance is sometimes fuzzy, and so is that between tax avoidance and evasion.

Under the self-interest and rationality assumptions, taxpayers would engage in evasion or avoidance so long as their incremental benefits from such activities exceed their incremental costs. However, many individuals and firms appear to be inherently honest and comply more fully than is anticipated by this approach. This suggests that taxpayers’ observed compliance levels depend not only on economic incentives but also on their sense of moral and social obligations. The determinants of tax evasion and avoidance broadly include:

- taxpayers’ sense of community association and perception of the tax system’s fairness;
- the tax rate (higher rates may induce evasion and avoidance, while the difference between personal and corporate rates encourages avoidance);
- opportunities to evade or avoid taxes (tax withholding and third-party reporting reduce evasion, while access to skilled tax practitioners increases avoidance);
- tax practitioners’ approach to reporting decisions;
- taxpayers’ compliance costs;
- tax administrators’ effectiveness (including detection, penalty, and enforcement).

In developing countries, entry into the formal economy may be blocked by legal, regulatory, and bureaucratic barriers. This blockage gives rise to tax evasion and avoidance.
The extent of tax evasion and avoidance can be approximated by the tax gap, which is the difference between the tax that is meant to be paid and that which is paid. The quantification of the tax gap, especially tax avoidance by businesses, is beset with both conceptual and empirical difficulties. Numerical estimates nevertheless suggest that tax evasion and avoidance are serious in industrialized countries. In the United States the federal tax gap (which includes tax evasion, unintentional errors, nonfiling, and tax underpayment) in 2005 was estimated by the U.S. Treasury to be 14 percent of the total federal tax revenue or $345 billion, most of which is attributable to underreporting of individual incomes (U.S. Treasury 2006). Studies of the black market economy suggest that, generally speaking, countries in the Organisation for Economic Co-operation and Development (OECD) face even higher relative tax gaps than the United States. Although there are no reliable estimates of tax gaps in industrializing countries, it seems plausible to argue that, compared with developed economies, developing nations suffer higher relative tax gaps because of their poorer tax administration and larger informal sectors.

TAX INCIDENCE
The objective of tax incidence analysis is to determine who ultimately bears the burden of a tax. It is therefore an important concept for evaluating the equity of the tax system.

Statutory incidence assigns the burden of paying a tax to either an individual or a business, depending on the tax. However, the burden of the tax may be shifted because individuals and firms adjust their behavior when taxes are introduced or changed. As a result, economic incidence (our subject here) may differ from statutory (“legal”) incidence. A simple example is an excise tax on gasoline. As shown in Figure 1, before a tax is imposed, the equilibrium supply ($S$) and demand ($D$) is achieved at price $P_0$ and quantity consumed of $Q_0$. If a $1 per gallon tax is imposed, the statutory incidence is borne by the consumer when he or she pays “at the pump.” However, the consumer will not pay the full amount of the tax, because the supplier will now receive a lower after-tax price per gallon. In effect, suppliers are faced with a new demand curve, $D'$, representing the price they will receive net of tax. This is denoted as the new demand curve, $D'$, in Figure 1. This demand curve is shifted down from the original demand curve, $D$, by $1 per unit. Per gallon of gas, the consumers now pay $P_g$ (the gross price), producers receive $P_n$ (the net price), and government receives $P_g - P_n$, or the amount of the tax ($T$). In the case demonstrated in Figure 1, the producer receives a lower price per unit than before the tax is imposed, and the consumer pays a higher price than in the no-tax case. Therefore, part of the tax is paid by consumers in the form of a high pump price, and part is paid by the producer in the form of a lower after-tax price received.

The economic incidence of a tax is largely determined by the elasticities of supply and demand, that is, by

---

**Example of tax incidence**

```
v
---

**Figure 1**
the change in the quantity consumed or produced when
the price of that good changes because of the imposition
of the tax. When the price elasticity of supply is very
small, the supply curve becomes more vertical and the
supplier tends to bear a larger portion of the burden of
the tax. When demand is very price inelastic, the consumer
tends to bear a larger share of the burden of the tax
(because there are few substitutes for the taxed good). This
type of analysis can also be done for taxes on factors—that
is, for taxes levied directly on labor and capital, such as a
.corporate profits tax or a payroll tax.

The analysis of tax incidence becomes more compli-
cated when we consider the impact of a tax in one market
on the supply and demand for goods in other markets.
Arnold Harberger (1962), a pioneer of the study of gen-
eral equilibrium tax incidence, demonstrated the theory
that taxes levied in one market can be borne by produc-
tive factors in another market. Harberger's model evalu-
ated the impact of a corporate income tax as a tax on
.capital in one sector of the economy (a "partial factor
tax"). By using a model in which the demand and supply
for output adjusted to a new equilibrium after a tax was
imposed, the impact of a corporate income tax on the price
of capital, labor, and output could be analyzed. The results
show that, depending on the elasticities of demand and
supply and the ability of producers to substitute labor for
capital in the production process, the burden of a cor-
porate income tax could be fully or partially borne by labor
or capital, or shifted forward in terms of higher output
prices. Harberger's model has been used since the 1960s to
estimate the burden of taxes, and it is also a model for ana-
lyzing the excess burden or "welfare loss" of taxes.

Even more complicated, intertemporal models that
consider the incidence of taxes over a lifetime have been
developed using sophisticated models of the economy.
John Shoven and John Whalley (1984) were among the
first economists to use computer models to analyze the
incidence of a system of taxes. These types of models are
now regularly used as a means to incorporate many mar-
kets into the tax incidence analysis.

Joseph Pechman and Benjamin Okner (1974) pro-
duced one of the first comprehensive incidence analyses of
the U.S. tax system, using incidence assumptions based on
general equilibrium results. They compared the distribu-
tion of income before and after taxes (imposing various
assumptions about the economic incidence of the tax) and
showed that at that time, the tax system had little impact
on the after-tax distribution of income. The Congressional
Budget Office produces regular analyses of the distribution
of the burden of U.S. federal taxes. Their 2006 analysis
shows that when all federal taxes are considered, the tax
system is somewhat progressive—that is, as incomes
increase, so too does the percentage of income paid in tax.

Tax relief is as old as modern-day government and is
primarily born out of a government's genuine concern to
bridge the wide gap between low-income and high-
income earners by exempting those earning below the
national minimum income from paying tax. Tax relief is
also often meant to protect local infant industries by
giving them tax holidays so they can better compete with
foreign companies. In addition, tax relief can be informed
by the need to redirect the economy toward a path of
balanced growth and development. In this light, tax relief
can be a useful tool in the hands of economic planners
who wish to effect necessary adjustments in develop-
ment parameters so as to achieve projected development
objectives.

Tax relief is premised on the belief that it will be used
for policing the economy and for bridging the gap
between local industry and foreign industry. In addition,
tax relief is seen as having the effect of stabilizing an econ-
omy, since a rise in the tax rate is likely to encourage work-
ers to work less, knowing full well that they will be taxed.
Tax relief may also stimulate the economy by raising the
aggregate level of savings and consequently investment.

Empirical evidence shows that tax relief is often
granted to individuals and corporate organizations who
are victims of natural disasters. Tax relief may also be
granted to citizens of states involved in bilateral or multi-
lateral trade agreements as concessions in response to their

TAX RELIEF
The term tax relief is widely used to refer to tax cuts, tax
rebates, tax subsidies, tax breaks, and tax write-offs that
reduce the amount of tax due or otherwise provide con-
cessions to taxpayers. Usually, tax relief is targeted toward
income and ownership taxes, consumption taxes, com-
modity taxes, and taxes on business establishments in
apparent need of such financial makeups.

Tax relief is premised on the belief that it will be used
for policing the economy and for bridging the gap
between local industry and foreign industry. In addition,
tax relief is seen as having the effect of stabilizing an econ-
omy, since a rise in the tax rate is likely to encourage work-
ers to work less, knowing full well that they will be taxed.
Tax relief may also stimulate the economy by raising the
aggregate level of savings and consequently investment.

Empirical evidence shows that tax relief is often
granted to individuals and corporate organizations who
are victims of natural disasters. Tax relief may also be
granted to citizens of states involved in bilateral or multi-
lateral trade agreements as concessions in response to their
development needs. For example, third world countries such as Gambia and Nigeria have been granted tariff concessions from GATT (General Agreement on Tariffs and Trade).

Tax-break programs may also help reduce the tax obligations of homeowners. In fact, some countries may offer tax relief to individuals who rent the property in which they reside and also to individuals earning a certain level of income. The Republic of Ireland, for example, offers such concessions to renters.

In some cases, tax relief may increase national income because it may encourage more work, saving, investment, risk taking, and entrepreneurship. If taxes are excessively or inappropriately levied, then a tax reduction may motivate people to be more productive and create wealth. Moreover, when people earn more income, they are able to spend more and save more.

Tax relief has been widely criticized for being politically popular despite a lack of clear economic benefits from such policies. After all, what is the rationale for granting tax relief that in the long run will be withdrawn? Tax relief is also criticized for having adverse effects on the economy in the long run. In technical terms, the government faces an intertemporal budget constraint, which means that when taxes are cut, other offsetting adjustments are required to make up for the cut. If the government decides to raise taxes later, effectively making the tax cuts temporary, the initial tax relief could lead to lower economic output over time. Tax cuts put money in people's pockets, but they do not pay for themselves. The government eventually has to pay its bills, and taxes are the primary source of government revenue.

TAX REVOLTS
Tax revolts are interesting because taxation—a claim made upon the property of individuals—is one of the two distinguishing features of government, the other being its monopoly on the legitimate use of force. Thus, when citizens rebel against taxes, their actions may represent something far more fundamental than when they reject other kinds of public policies. Tax revolts are also interesting because they seem to be ubiquitous. Peasant revolts against land taxes have been documented from medieval Japan (White 1995) to contemporary Africa (Kelsall 2000) and China (Bernstein and Lu 2003). In Europe, voters have rebelled against both British prime minister Margaret Thatcher’s poll tax proposal that was regressive in incidence by bearing relatively more heavily on the poor than the wealthy (Burns 1992) and the progressive tax program of the Danish welfare state (Kirschelt 1997). And in the United States, the tax rebellion label has been applied to both the revolution of 1776, as illustrated by the Boston Tea Party, and the wave of tax reduction and tax caps adopted following California’s passage of Proposition 13 in 1978 (Sears and Citrin 1985).

Given the importance and ubiquity of tax revolts, it is not surprising that scholars have spent considerable time trying to explain why they occur. The very ubiquity of “tax revolts” suggests that not all of the events so labeled are the same kind of phenomenon. Therefore, no single explanation is likely to explain all tax revolts. Indeed, there seem to be several different kinds that vary in terms of the breadth of issues they address. At the narrowest level are voter rejections of specific referendum proposals to raise taxes or to adopt bond issues. In such cases, the issue is narrowly defined and the forces determining voters’ decisions are typically the same kinds of socioeconomic, attitudinal, and partisan variables found to be important in day-to-day politics (Cataldo and Holm 1983; Listhaug and Miller 1985). Thus, we do not need a special kind of explanation for some kinds of tax revolts. Indeed, it is not clear that such events constitute “revolts,” since voters are making their preferences heard on specific policies through routine mechanisms of political choice.

The tax revolt label, in contrast, usually refers to something more unusual or unexpected. In some cases, as in voter agitation over property-tax-assessing practices in California in the early 1970s, the focus of the tax revolt might still be narrowly defined as a tax issue, even if it was a somewhat unusual sort (Paul 1975). But in other cases, tax revolts may represent a more general challenge to the government in power, as seems to have been the case in Britain’s rejection of Thatcher’s regressive poll tax and the Danish People’s Party rejection of high levels of progressive taxation to support the welfare state. Even further, tax revolts may represent a rejection of the political regime...
itself, as some argue is the case with rural protests in China. In these broader episodes of tax revolution, taxes are merely the specific focus of a larger rebellion. Given this complexity, determining what citizens are saying when they revolt against taxes is easy neither for the politicians who must respond to rebellions or for scholars trying to explain them.

Perhaps the broadest and most unusual type of tax revolt occurred in the United States during the late 1970s and early 1980s, starting with the passage of California's Proposition 13. This event was certainly unusual. Californians had rejected by large margins two similar proposals in the previous decade. And nationally, while no tax revolt referendum had passed prior to Proposition 13, none failed in the ensuing five years, and none were successful thereafter. Within a short period, more than one hundred scholarly papers appeared purporting to interpret what voters were saying to politicians. These explanations covered all of those noted earlier for other tax revolts, from a rejection of big government (Rabushka and Ryan 1982) to symbolic racism (Sears and Citrin 1985). But none proved capable of explaining the boom and bust cycle of the great American tax revolt (Lowery and Sigelman 1981). Or rather, all of these explanations were true to some degree. That is, the U.S. tax revolt was an unusual kind of comprehensive single-issue politics in which grievances of all kinds were linked to a single policy solution—limiting taxes (Lowery 1982). In effect, tax revolution was a magic bullet that would solve a problem, no matter what the problem was. Once the tenuous connection between the many different kinds of grievances motivating voters and the specific tax proposals before them became obvious, support for the movement collapsed.

Irrespective of their origin, the consequences of tax revolts can be significant. Thatcher left office shortly after the failure of her poll tax proposal. In Denmark, the tax revolt movement evolved into the Danish People's Party, which has since taken a lead in promoting anti-immigration policies. In the United States, few tax revolt referendums actually cut taxes. Indeed, only one state followed California's Proposition 13 by sharply cutting property taxes. The other nineteen state referendums actually cut taxes. Indeed, only one state followed California's Proposition 13 by sharply cutting property taxes. The other nineteen state referendums actually cut taxes during the tax revolt period imposed fiscal caps that set limits on the future growth of government. But nearly all state legislatures cut taxes during this period so that for the first time in decades aggregate state tax burdens actually declined for several years. And the results of tax-revolt-induced policies can sometimes be surprising. As yet, the fiscal caps adopted by the states have not seriously impinged on government spending, although they may do so in the future (Cox and Lowery 1990). As for the hundreds of tax cuts adopted by legislatures, their consequences were often surprising. State government budgets were, as expected, highly constrained for several years. But state taxes were also marginally less complex and more progressive and elastic after the tax revolt than before, something that neither supporters nor opponents of tax cut proposals had anticipated (Lowery 1986).

**TAXATION**

Taxation is as old as recorded history. The earliest forms of writing, pictographs from the ancient Near East, are records of taxpayer accounts, paid and owed, to the king. *Taxation* is the taking of economic resources by a political entity from an individual or collective who is subject to its
authority. It is a *taking* in that taxation is not a freely voluntary exchange, because resources are given under threat of coercion. **Economic resources** can take the form of money, goods, or service. **Political entity** refers to an individual (chief, prince), group (tribe, caste), or institution (state, government) that makes claims on and decisions for those from whom economic resources are sought. Their *authority* to claim economic resources is derived by consent, law, or force. The subjects of taxation are usually territorial based, including social collectives (tribes, villages, colonies, castes), economic collectives (guilds, mercantile companies, incorporated businesses), and individuals and households.

There are two general forms of taxation, direct and indirect. Direct taxation refers to tax claims made on fixed entities, such as a person, a business, land, and property. Indirect taxation refers to tax claims made on economic transactions, such as the sale of goods and services, trade, and commerce. For much of preindustrial history, taxes were direct, such as the poll tax. They were imposed on collectives and paid in kind with labor or goods (a percentage of agricultural harvests). With the rise of capitalist cash economies in the modern period, taxation increasingly was directed toward money and financial assets. The modern state has shown a preference and capacity for indirect taxes as well as direct taxes claimed from individual households and business collectives.

Taxation is a type of exchange relationship between a political entity and its claimed subjects. Exchange is what distinguishes taxation from plunder. The political entity is supposed to provide something in exchange for economic resources. In the earliest forms of taxation, political entities claimed tribute in exchange for protection from physical harm, both from the political entity itself and from others in warfare or robbery. As the relationship evolved historically, taxation became more varied in form and routinized in collection; in exchange, political entities provided more public goods, such as dispensation of justice, enforcement of law and property rights, establishment of economic infrastructure and cultural institutions, and provision of social and economic welfare goods. Some taxes are imposed not just to raise revenue but also to promote or discourage social behavior. For example, a reduced tax burden is meant to encourage charitable donations, while higher tax rates are meant to discourage smoking and drinking.

Taxation serves as the arena where power and wealth collide and connive in society. Each society develops its own system of distribution of tax burdens, progressive or regressive, which inevitably penalizes some and benefits others. Quasi-voluntary compliance occurs when political authorities succeed in providing sufficient goods in exchange and maintain a perception of fairness in the tax burden and a threat of coercion against those who do not pay. If these three factors are not in place, the tendency for evasion and noncompliance increases. Also income tax compliance was enhanced when employers were made to share responsibility for payment with employees. Tax burdens are sometimes effectively hidden in the final costs of goods. Resistance to the revenue claims of political authorities in the form of tax revolts provides some of history’s most notable political conflicts, including the English civil war, the French Revolution, and the American War of Independence.

**TAXES**

Taxation is the principal means by which governments get the resources to pay for activities such as armed forces, a court system, a health care program, and programs aimed at transferring resources to the destitute or the elderly. Taxation is not, however, the only means by which a government gains control of resources; for example, many countries draft people into the military. Among developed countries, taxation accounts for between 25 and 50 percent of national income. Taxation in developing countries generally raises substantially less than this, primarily due to the difficulty the tax authorities encounter in collecting taxes. Although tax receipts in many countries fall well short of covering current expenditures, the resulting deficits do not imply that the expenditures are costless; payment is simply delayed, and future generations bear the costs of the expenditure.
Taxation is as old as government itself. Indeed, the first known written records, made by the Sumerians about 5,000 years ago, are apparently tax records. Before money was widely used, taxes were paid in kind with grain, cattle, labor, and other valuable objects. Compulsory labor is the earliest form of taxation for which records exist; indeed, in the ancient Egyptian language the word labor was a synonym for taxes.

In Europe before the seventeenth century, most taxes were levied directly on people, depending on their status in society or on the land they owned. About that time, new taxes arose that were associated with the rising tax bases related to commerce, transactions, and urban markets. Some advocated such taxes as a way of introducing equality in taxation, because the privileged classes had managed to obtain virtual immunity from the existing status-based tax system.

Beginning in the nineteenth century, the growing scale and cost of war greatly expanded the revenue needs of many Western countries, and the tax systems expanded to keep up with these needs. The modern income tax began in Great Britain around 1800 to help pay for wars with France. Financing wars was then the major expense of government—from the twelfth to the nineteenth century, between 75 and 90 percent of the English government’s expenditure went to financing wars. The income tax was also a response to a concern that a tax system that relied on land as a tax base was failing to reach the growing commercial wealth and income that arose during the Industrial Revolution.

Resistance to taxes was a theme of the American Revolutionary War (1775–1783). In keeping with that spirit, taxes in the United States were relatively low until the twentieth century and are still among the lowest of all developed countries. In 1900 U.S. federal taxes amounted to just 3.1 percent of gross domestic product (GDP), while state and local taxes comprised another 4 to 5 percent. The U.S. income tax was introduced in 1913, after the passage of the Sixteenth Amendment to the Constitution, which set aside the constitutional provision that all direct taxes must be levied across states in proportion to their population.

The role of the U.S. federal government expanded greatly during the first half of the twentieth century, and by 1943 federal taxes increased to 19.7 percent of GDP. World War II (1939–1945) was clearly the critical juncture, although the New Deal years of the 1930s were also important. Many programs, particularly Social Security, were introduced during the 1930s and would require much higher taxes in later years. By 2003 federal tax receipts (including social insurance payroll taxes) amounted to 17 percent of GDP with state and local taxes adding another 8.8 percent. The total share had been roughly constant since the 1970s, but since 2001 federal taxes as a share of GDP have fallen notably due to a series of tax cuts enacted during the George W. Bush administration.

In modern tax systems, a wide range of activities and circumstances can trigger tax liability—the purchase of a good from a retailer triggers a sales tax, the payment of wages for a business to a worker triggers an income tax, or the passing of wealth from one generation to the next triggers estate and inheritance taxes. Although there are a large variety of taxes, certain kinds predominate. Among developed countries, which raise on average about 37 percent of GDP in taxes, slightly more than one-third of tax revenue comes from income taxes; slightly less than one-third comes from various taxes on consumption, including value-added taxes remitted by all businesses; and about one quarter comes from social insurance taxes. The United States is also the only country of the Organisation for Economic Cooperation and Development, a group of thirty developed countries, without a value-added tax.

On average, poorer developing countries collect taxes that amount to a substantially lower percentage of their national income. Of the tax revenue they do collect, a smaller share comes from income taxes and a larger share from both consumption taxes and, especially, taxes on international trade. The reliance of developing countries on trade taxes reflects the relative ease with which goods can be observed and valued as they cross international borders, which is important in countries where administrative resources are scarce. It also reflects the use of import taxes as a deliberate economic strategy to promote domestic industrial development, as well as the prevalence of easily taxed exports of primary products such as oil, food, and industrial crops. This lower reliance on income taxes is largely due to the difficulty of collecting income taxes in countries with large informal sectors; unlike developed countries, only a small proportion of the workforce is employed by well-established, financially sophisticated companies whose existence facilitates collection of taxes on the income of both businesses and employees.

There are two key aspects to all taxes: Who bears the burden, and what is the effect on the economy? Ascertaining who bears the tax burden is not simply a matter of keeping track of who writes the checks to the government. For example, in the United States most of the income tax liability of employees is remitted by employers in the form of withholding, although it is widely believed that it is the employee, not the employer, who bears the burden through lower take-home pay. The filing of an employee’s tax return reconciles his or her
actual tax liability to what has already been remitted, on the worker's behalf, by the employer.

Taxes can also impose burdens by changing the prices of what people buy, as occurs with cigarette taxes. Taxes can even have an impact on individuals buying untaxed goods. For example, a tax on butter may cause some consumers to switch to margarine, driving up the price of margarine and shifting some of the tax to people who prefer margarine for health reasons.

Some types of taxes, such as the corporation income tax, are legally owed by a business entity, but the tax burden will be shared among the company's shareholders, workers, and customers to the extent that the company is able to “pass on” the tax burden by, for example, paying lower or charging higher prices for their products. Assessing the burden of the corporation income tax is one of the most controversial questions in the study of taxation, made more difficult by the advent of multinational corporations that have operations, customers, and shareholders in many countries.

The question of who should bear the burden of taxes is separate from who does bear the burden. It is a perennially contentious issue for which there is no right or wrong answer. One aspect is how the burden should be shared across income classes, an issue often referred to as tax progressivity. Intuitively appealing but vague principles—for example, taxes should match the benefits one receives from government activities, or taxes should equalize sacrifice—do not offer much practical guidance, and modern economics has for the most part given up on refining such principles to instead focus on the consequences of different levels of progressivity. Moreover, it is not clear why, in assessing the distributional consequences of government, it makes sense to focus on tax progressivity rather than the progressivity of what the government provides its citizens and how it assesses taxes to pay for those programs.

Aside from progressivity, tax systems should avoid arbitrary distinctions in tax burden based on people’s tastes or characteristics, whether intended or capricious. In the past, such arbitrary taxes have been imposed on minorities; examples include the poll tax collected from Jewish communities in the Holy Roman Empire and the poll tax levied on non-Muslims in the eighth-century Abbasid caliphate of Persia. Modern tax systems often make tax-burden distinctions among families of the same income level, based, for example, on such factors as family size, charitable inclinations, or tastes for cigarettes.

The second question to ask about any tax system is what costs it imposes. The first and most obvious cost is that every dollar of taxes remitted to the government leaves one less dollar for taxpayers to spend on goods and services. For this reason, a responsible government will only raise taxes to provide programs whose value exceeds the private consumption that is given up.

But there are costs over and above the money taxed away. For one thing, collecting taxes requires a substantial bureaucracy. The Internal Revenue Service (IRS) budget is over $10 billion per year, although that amounts to only about 0.5 percent of the revenue it collects. Dwarving that are the costs borne directly by the taxpayers—called compliance costs—which include the value of their time spent on tax matters and money spent on tax software and professional tax preparers and planners. This cost has been estimated to exceed $100 billion a year for the U.S. income tax system, ten times the administrative cost for all taxes combined and about 10 percent of revenues collected.

Administration of a legitimate, nonarbitrary tax system is facilitated when there are observable, measurable things that can serve as tax bases. For example, it is notoriously difficult to enforce taxes on food products grown and consumed by farmers and on the income of self-employed individuals. Most modern tax systems rely on businesses that withhold taxes on employees’ earnings and provide information reports to the tax authority that can be matched with employees’ tax returns. Withholding and information reports are supplemented by random audits, with penalties for noncompliance. In many countries, the employee-withholding system is exact and final so that no tax return need be filed by most employees; the British pay-as-you-earn system is an example.

In spite of these measures, substantial tax evasion occurs. According to the IRS, about 16 percent of the federal taxes that should be paid are not. The noncompliance rate varies widely by the type of income; it is less than 2 percent for wages and salaries and as much as 50 percent for self-employment income, the stark difference reflecting the availability of withholding and information reports for the former but not the latter type of income.

Taxes impose another kind of cost on an economy because they alter the costs and rewards of various behaviors. For example, both income and consumption taxes reduce the incentive to work by reducing the consumption reward per hour of labor supplied to the market. Income taxes, but not consumption taxes, also reduce the reward and therefore the incentive of individuals to save and businesses to invest. These behavioral responses represent costs because they channel resources in socially unproductive directions. For example, from society’s point of view it is costly if income taxes dissuade someone from joining the labor force. Much economic analysis has tried to quantify these behavioral responses; the consensus view is that the overall labor supply response is not large and the saving response is not well understood, but certain other behaviors, such as the timing of capital assets sales
to anticipated tax changes, are highly responsive to the tax system. The bigger the behavioral response, the higher the economic cost per dollar raised. Some have estimated that, all in all, the behavioral responses to the U.S. income tax system generate an extra forty cents of social cost for every additional tax dollar raised.

**TRADEOFFS**

Tax policy is controversial because the objectives often conflict. Although the economic costs could arguably be reduced by making the tax burden less progressive (i.e., reducing how much the tax burden rises with income), many would find such a system to be an unfair shifting of the burden toward low-income people. Simplifying the tax system could save substantial administrative and compliance costs, but a simplified system might render the tax burden less finely tuned to individual circumstances. Many of the debates about tax policy involve such choices. For example, would lowering taxes on entrepreneurial income stimulate enough economic activity to offset the fact that (successful) entrepreneurs are often among society’s wealthiest citizens?

The twentieth-century expansion of the role of government, and the associated need for more tax revenues, seems to have peaked in the 1980s, and on average the worldwide ratio of tax collections to GDP has not changed much since that time. Looking ahead, as national economies become more interconnected, it may become more difficult to collect taxes without substantial cross-country cooperation. Furthermore, governments may compete to attract businesses by offering lower taxes. Some view this development as a dangerous “race to the bottom” that will undermine the ability of governments to provide public goods and social insurance, while others applaud it as a way to discipline otherwise profligate governments in the same way that competition among companies promotes cost-minimizing business operations.

Especially in the last two decades, the U.S. income tax system has become much more than a way to raise revenue; it also delivers a wide range of social programs. Thus, it is misleading to associate government expenditure programs with what the government does and the tax system with how it pays for what it does because much of what government does is achieved via the tax system. For example, the U.S. income tax subsidizes charitable giving by making it deductible from taxable income. It also promotes homeownership through its favorable tax treatment, and it delivers the country’s biggest antipoverty program via the earned income tax credit. These programs add to the complexity of the tax system, and thus to its administrative and compliance costs, and the constituencies that benefit often oppose efforts to simplify the tax system that would eliminate these programs.

**TAXES, PROGRESSIVE**

A progressive tax is one for which the rates vary according to one’s ability to pay. Thus, those who possess more highly valued economic assets, such as property or income, are taxed at a higher percentage than those whose economic assets are valued less.

Historically, progressive taxes were exceptional in that they were aimed at an elite class that was often exempt from paying certain taxes. In ancient times, progressive taxes were often associated with extraordinary circumstances, especially military campaigns. Republican Rome’s tributum is an example of a war-related progressive tax.

Progressive taxation became a norm in the modern period with the emergence of a direct relationship between the state and individuals in society. The increased demands of modern states to raise revenue from individuals led to the introduction of citizenship, which brought enhanced political and legal rights to the individual and greater obligations of the individual to the state. These obligations included new revenue claims, such as personal income, capital gains, and inheritance taxes. These individual-based taxes form the basis of a progressive tax.
scheme, which is applied at ascending rates relative to the economic value of the targeted assets. The United States’s personal income tax was meant to be progressive, with top marginal rates reaching above 90% in the 1960s.

The progressive tax was created as a fiscal means by which political authorities gained greater access to the economic resources of the wealthiest members of society. The arguments in favor of progressive taxation stress a sense of social fairness in that the wealthiest members of society have a disproportionately higher ability to pay for those public goods and services from which they benefit, directly and indirectly. These arguments are associated with the ideological programs of political populism and socialism. By contrast, the arguments against progressive taxation stress a sense of individual fairness in that those with wealth are being penalized for their personal ingenuity, risk taking, labor, and luck. These arguments are associated with the ideological programs of free-market capitalism and neoliberalism.

In the advanced industrial economies, progressive tax systems went into place incrementally in the late nineteenth century. By the mid-twentieth century, they reached their limits with extremely high marginal rates and the spread of the progressive tax burden to the middle classes. This tax policy practice caused unintended negative consequences, including a rise in tax avoidance and capital flight and a decline in economic productivity and growth. Progressive taxation was viewed critically less as a fair means of allocating the tax burden and more as an unfair means of reallocating wealth. In the late twentieth century, a political reaction was led by Margaret Thatcher, the Conservative prime minister of the United Kingdom, and Ronald Reagan, the Republican president of the United States, who began a reverse trend to ease the tax burden on the wealthy with tax reforms of a more modified progressive and even regressive character in the advanced industrial economies.

SEE ALSO Taxes; Taxes, Regressive

Gerald Easter

TAXES, REGRESSIVE
A regressive tax is one that has a disproportionately more negative economic effect on the poorer members of society than the wealthier members. Regressive taxes usually have fixed rates, and are thus not sensitive to one’s ability to pay. Likewise, a tax is considered regressive if the wealthy are able to avoid compliance more readily than the poor.

Because of the limited capabilities of premodern political authorities to assess value and monitor transactions, the earliest forms of taxation tended to be regressive. The preference was for taxes that were relatively simple to compute and collect. The head tax, such as the British poll tax and the Russian soul tax, was a direct tax with regressive distributional consequences. It was a levy applied at a fixed rate on each individual, regardless of income and property status. Likewise, the French gabelle, or salt tax, was an indirect tax with regressive distributional consequences. This tax was set at a fixed rate and administered by royal agents in the sale of this consumption necessity, even though the cost was a significantly greater burden for poor households.

In the modern period, regressive tax schemes remained common in economies with narrow elites, wide income disparity, underdeveloped industrial bases, and authoritarian political regimes. In the advanced industrial democracies, however, regressive taxation eventually fell out of favor. This was a consequence of political reforms that expanded voting rights, leading to the enactment of more progressive forms of taxation. An additional factor was an increase in technological and bureaucratic capabilities that enabled modern governments to keep track of economic activities and income sources.

More recently, arguments have gained ground in favor of tax reforms with regressive tendencies in the industrial democracies. Fiscal arguments stress the complex and opaque nature of contemporary tax systems and contend that the simplification of tax policy would facilitate taxpayer compliance and state collection. Economic arguments stress that a more regressive tax code would create greater incentives for the investment and activity that expanded voting rights, leading to the enactment of more progressive forms of taxation. An additional factor was an increase in technological and bureaucratic capabilities that enabled modern governments to keep track of economic activities and income sources.

National sales taxes and flat rate income taxes are the most common types of tax reforms that have regressive distributional consequences. The European economies rely heavily on the value-added tax (VAT), which is a kind of national sales tax, where a fraction of the total tax is added at each stage of production and distribution, instead of all at once at the last stage. If the price of necessary goods and services is relatively constant, then a sales tax is regressive. To illustrate, Denmark has a 25% VAT without exception. Thus, if two persons buy an identical
bag of groceries each week for 20 Danish krones (DK), they both pay DK5 in VAT. But if the first person’s weekly income was DK100 and the second’s was DK1000, then the first person paid a higher percentage of their weekly worth (5%) than the second person (0.5%). Most European governments, however, provide exemptions on the VAT for basic necessities. Support for a flat income tax has grown in Europe and United States with the enactment of flat tax rates in the transition economies of central and eastern Europe, including Estonia, Slovakia, and Russia. The flat tax was instituted in the transition economies largely because of the weakness of the state tax administration to monitor and extract revenue from the emerging private sector and households.

TAYLOR, LANCE

1940–

Lance Taylor is an economist who has contributed widely to development economics and nonorthodox economic theory. After receiving his PhD in economics at Harvard in 1968, he taught at the leading economics departments of Harvard and Massachusetts Institute of Technology and then moved to a self-proclaimed heterodox department at the New School, a university in New York.

Taylor’s early work deals with mainstream development topics, such as the econometric and simulation modeling of changes in the sectoral distribution of production in the course of development. He also explored development planning models, including research on numerical methods in nonlinear programming. While working in Chile in the 1970s, Taylor was exposed to the heterodox structuralist ideas of the United Nations Economic Commission for Latin America, and he observed firsthand how distributional conflict affects the economy. His subsequent models are more heterodox, departing from the orthodox neoclassical “closure” with full employment of labor; instead, they stress the role of aggregate demand and distributional conflict.

These ideas crystallized into what Taylor (1983, 1991) calls the structuralist approach to development macroeconomics. The starting point is a model of demand-determined output along Keynes-Kalecki lines that examines the relationship between output growth and income distribution. The model is then extended to deal with interactions between industrial and agricultural sectors, asset markets and financial fragility, wage-price inflation due to distributional conflict, fiscal constraints on growth, international issues including debt and foreign exchange problems, and the interaction between rich and poor countries. Drawing on these theoretical contributions, Taylor, with his colleagues, developed structuralist computable macroeconomic models for a number of developing countries. From a sole focus on developing countries, Taylor’s (1991, 2004) emphasis shifted to macroeconomic theory more generally, as applied to both developed and developing countries. Thus, while in mainstream economics there has been a trend toward applying theories constructed for developed countries to development issues, for Taylor there is a reverse tendency.

Taylor also worked extensively on economic policy in developing countries, leading numerous projects with collaborators from many countries. He provided some of the most rigorous and comprehensive criticisms of International Monetary Fund stabilization policies (see Taylor 1988). He also addressed the macroeconomic, distributional, and environmental consequences of economic liberalization policies adopted by developing and postsocialist economies, as well as the impact of such policies on the international financial system. This work not only draws on his theoretical models, but also his broader political economy perspective and his deep knowledge of the institutions of developing countries.

Taylor’s opposition to neoliberal one-size-fits-all policies has been very influential, both because of his firm analytical grounding and his insistence that appropriate policies should take into account the specific structures and institutions of individual countries. His theoretical contributions, however, have not received the attention from mainstream economists that they deserve because of his departure from their protocol of using optimization as a basis of economic theorizing. But his structuralist alternative—of starting with macroeconomic accounting identities, then adding appropriate equations representing the behavior of relevant groups and the institutional attributes of particular economies based on careful historical and empirical work—may yet prove to be a more productive way of analyzing the operations of actual economies.

TAYLOR RULE

In the late 1950s the Phillips curve became the dominant policy model, prescribing a trade-off between the wage and inflation rate against the unemployment rate. In the 1960s the parameters of the Phillips curve began to drift. Adaptive expectation with and without the natural rate and NAIRU (nonaccelerating inflation rate of unemployment) hypotheses was added to the curve. Later, the rational expectations hypothesis, which brought into question the assumptions of full information and variation between the actual and theoretical parameters of models, became popular. In 1979 and 1993, to improve predictions in line with the Phillips curve, the American economist John B. Taylor (b. 1946) introduced the Taylor curve, which specifies variance, rather than rate, in output and inflation to explain the great moderation in macroeconomic data since the 1970s.

Taylor advanced policy arguments—including that the variance of inflation and real gross domestic product (GDP) could be reduced to minimum levels—and empirical justifications for the Taylor rule. The rule is, where $r$ is the federal fund rate, $p$ is the inflation rate, and $y$ is the percentage deviation of real GDP from a potential level. The Federal Open Market Committee (FOMC), the committee within the Federal Reserve that sets the target federal fund rate, can use this rule as a guide. The evidence shows a high correlation between the actual federal fund rate and estimates from the rule for the period from 1987 to 2005, with peaks and troughs matching up closely in most years.

The Taylor rule has many novel features. It transcends the “either/or” nature of the rules versus discretion debate by making room for discretionary policies as well. It is neither a fixed rule nor one that expands the money supply to approximately the growth rate of output as Milton Friedman (1983) proposed. A fixed policy rule would not be useful to the FOMC because, besides lacking a feedback mechanism, it would shun the Fed’s responsibility to stabilize cyclical swings, rendering the Fed passive. Even when the public acts with rational expectations and policymakers have full information, the Fed may want to choose a time-inconsistent or suboptimal policy such as when a change in administration occurs. A new administration may want changes, encouraging the FOMC to choose sequentially, such as setting interest rate targets meeting-by-meeting.

Another novelty is that the Taylor rule is not necessarily optimal in the sense of a single point on the trade-off in the production-possibility-like frontier. While Robert M. Solow argued for precise estimates, Taylor inferred robust estimates for a broader group of models. Generally, rules are considered prescriptive or normative in nature, as Taylor originally intended them to be, but the Taylor rule turned out to be very descriptive as well.

One area for further research is to find the reliable equilibrium federal fund rate and potential GDP estimates in a more forward-looking environment. This may mean that changes in the money supply advocated by other rules should be considered. Just as patents require laws to encourage inventiveness, the Taylor rule requires commitment to make it credible. In the early twenty-first century, the Taylor rule is an active research program that is attracting much attention in the literature.

TAYLORISM

A traditional social science, sociology, informs this entry. Sociology is subdivided into areas of specialization that may overlap. Areas relevant to this topic include historical sociology, economic sociology, organizations and work, and theory.

The term Taylorism is synonymous with scientific management, both named after the American industrial engineer Frederick Winslow Taylor (1856–1915) and his 1911 monograph, The Principles of Scientific Management. Taylor provided the framework for a management philosophy and method and for the organization of work. He based his framework on scientific law, breaking work into parts and separating mental from physical labor. His principles involved the following: (1) Developing a science of production; (2) carefully selecting and training workers; (3) connecting the science and the workers; and (4) splitting responsibility between management and workers. Taylor’s ideas contributed to a movement across industrialized countries. The Germans called it the rationalization movement.

Taylor’s framework rested on the assumption that workers are motivated by money. Through his time-and-motion studies, he established specific standards for how long each particular job should take and which kinds of physical routines it should involve. These efficiency guidelines were used as bases against which each worker’s output was measured, and pay was calculated once workers were selected in terms of their work ethic and trained consistent with established standards. The greater the worker’s output, the more pay the worker received. Taylor’s equation incorporated breaks during the workday at specific intervals and for a specified length of time because he realized breaks increased productivity and workers’ stamina. He saw breaks as efficient and effective for both workers and management.

Management was charged with the mental work in this hierarchical division of labor. In planning rooms above the shop floor and sometimes housed behind plate glass windows, management delegated responsibility, designed products, set the production schedule, and checked performance.

As a consequence of Taylorism, the organization of production became compartmentalized and control became centralized. Product design and production were separated. Work became task specific and mechanical as workers were turned into quasi machines. According to some critics, deskilling resulted, and the engineering of workers replaced the engineering of materials. In addition, productivity declined.

This model of economic organization lends itself well to mass production, historically the dominant form of industrial production in the United States. It catered to waves of immigrants and a growing middle class. With its focus on efficiency, the model emphasizes quality over quantity and innovation. This focus affected even the design and production of American machine tools, necessary for the production of most other products. Machine tools were designed for convenience of operation and to minimize motion and the operators’ need for skill. These machine tools were adequate for mass production, but not for flexible production or custom production.

The negative outcomes of Taylorism are consistent with Adam Smith’s (1723–1790) concerns. While Smith embraced the division of labor because he believed when workers specialize, they become more productive, he emphasized that oversimplification of a worker’s tasks may have inhuman, demoralizing effects. Although famous for advocating a free market economy, Smith argued for government intervention if it is necessary for enhancing the quality of life, particularly for those with the least resources, to ensure the common good.

Karl Marx (1818–1883) preceded Taylor in history and did not address Taylorism specifically. Marxist theory, however, regards the mode of production as rooted in the economic system. Individuals must consume in order to survive, and they cannot consume unless they produce. They must therefore enter into relations they cannot control, such as economic relations. According to Marx, this differentiates them from nature, from their own kind, and leads to alienation. Marxist theory rejects Taylorism as a strident form of worker exploitation under capitalism that strips workers of control over their work. Workers become mere means to capitalists’ ends.

Fordism is a form of mass production linked to Henry Ford (1863–1947) of the Ford Motor Company during the early twentieth century. Fordism adopted the same principles as Taylorism, including the separation of mental and physical labor and the segmentation of work. Both pivot on quantity and speed. Using Taylor’s principles, Ford introduced the assembly line, which automated the control of work. The speed of the assembly line controlled workers’ movements and output and dictated the timing.
of breaks during the workday. The method of Fordism preceded the social scientific concept of Fordism, a term coined by the French regulation school. This school arose in the context of the first significant post-war recession during the 1970s as a critique of the capitalist mode of regulation, regarded as co-opting social and political life.

Globalization means interdependence of nations, groups, and individuals around the world. One dimension of such interdependence is economic globalization, which is fueled by capital’s search for cheap labor internationally. Cheap labor equals cheap technology; poor countries provide cheap labor and rich countries provide technological innovations. This division of labor between poor and rich countries represents a separation of physical from mental labor that is rooted in Taylorism. Technological innovations, like the Internet, facilitate speed by compressing time and space. A more holistic, flexible, and less hierarchical approach to the economic enterprise is required, however, for continuous innovation. Such an approach may provide the potential for the reintegration of physical and mental labor across the globe.

TEA INDUSTRY
Modern tea comes from Camellia sinensis, a tree native to China and India. In today’s commercial tea trade there are three main varieties of Camellia sinensis: China, Assam (northeastern India), and Cambodia, each named for the area in which it was first grown commercially. The China variety is a hardy, 3-meter-high bush with a useful lifespan of one hundred years. The Assam and Cambodia varieties are tall single-stem trees with a commercial life of forty years. Typically, tea trees are kept short through frequent trimming for easy plucking (i.e., the picking of tea leaves).

Although tea can be grown in a variety of agroclimatic conditions, the best teas are grown at altitudes between 1,000 and 2,000 meters.

Green leaf, the farm product, is sent for processing at tea factories and becomes made tea—sometimes called black tea or dry tea—the internationally traded commodity. Tea companies then blend tea from various origins to make what is often called packed tea, the beverage that consumers drink. The ratio of green leaf to made tea is about five to one, that is 5 kilograms of green leaf are required to make 1 kilogram of made tea. Three processing methods are used to convert green leaf to three types of made tea: black, green, and oolong (Forrest 1985).

To make black tea, tea leaves are spread on racks to dry and then put through a machine that breaks up the leaf cells, frees the oils, and ejects a twisted lump of leaves. These are sent to a fermenting room, where they are spread thinly and left to absorb oxygen. The leaves are then exposed to a continuous blast of hot dry air for fifteen to thirty minutes, which turns them black. Black tea accounts for three-quarters of global tea output and is supplied mostly by East African and South Asian countries.

Green tea has a less processed flavor than black tea. The leaves are steamed and heated immediately after plucking. Because the leaves are dried without going through fermentation, they remain green. After being separated by grade, the leaves are packed in chests lined with aluminum foil. Green tea, which accounts for a quarter of global tea output, is supplied primarily by China and to a lesser degree by Japan, Vietnam, and Indonesia.

Oolong tea is traditionally prepared in South China and Taiwan from a special form of the China tea plant—the chesima. It has large leaves and a distinct flavor. Preparation is similar to black tea but with a much shorter fermentation process. Oolong teas, which account for only a small fraction of the global market, are often scented with flowers.

While people often refer to almost anything steeped in hot water as “tea,” only Camellia sinensis is properly given this designation. Teas made with herbs and berries are more properly called tisanes or infusions. Leaves from several other plants are consumed like tea. For example, Paraguay tea, often called yerba mate, is made from the leaves of a species of holly found primarily in Argentina, Brazil, and Paraguay. The Indians of North Carolina used to prepare a tea called yaupon from the leaves of another holly-like tree. Trinidad tea is made from the leaves of the pimento or allspice tree.

PRODUCTION AND TRADE
Tea is produced in both tropical and temperate zones. Because it grows at high altitudes, it typically does not compete with food or other cash crops. Asia accounts for
about three-quarters of global production, Africa for half the remainder, and several Middle Eastern and Latin American countries for the rest. During 2002–2005 China and India produced more than half of the world’s tea (26 and 27 percent, respectively), followed by Sri Lanka (10 percent) and Kenya (9 percent). Global tea production during this period was 3.25 million tons.

Tea is produced by both smallholders and estates. Tea estates are owned by large companies producing large quantities of tea, normally exceeding 1,000 tons of made tea (sometimes as much as 10,000 tons). Tea estates employ both permanent and seasonal laborers. Often, the permanent laborers reside in living quarters within the estate and receive other benefits, such as basic health care and schooling for their children. The conditions for employment on tea estates are considered very good, and permanent workers are often considered to be “privileged” compared to their seasonal counterparts. Although wages are low compared to Western standards (about $2 per day), they are considered high enough for, say, Africa, where two working adults at this wage rate are able to lift a family of four to five above the poverty level. Conditions of employment are also considered good because estates, often owned by multinational companies, must adhere to international standards and scrutiny concerning wages, hours, and conditions of employment. In addition to the International Labor Organization which sets labor standards, numerous international and local non-governmental organizations and advocacy groups (such as the International Labor Rights Fund) monitor employment conditions.

Global tea production from 2000 to 2004 exceeded three million tons, valued between $4 and $5 billion annually. Growth in tea production, as high as 4 percent in the 1970s and 3 percent in the 1980s, slowed to 1.6 percent in the 1990s. Almost half of global tea production is traded internationally. Sri Lanka (22 percent), China (18 percent), Kenya (16 percent), and India (16 percent) account for almost three-quarters of world exports. The United Kingdom used to be the largest tea importer (during the 1960s it accounted for almost 40 percent of world imports, but by the early 2000s it accounted for only about 10 percent). The dominant tea importer is Russia, which accounted for 12 percent of world imports in 2005.

**TEA PRICES**

Unlike most primary commodities whose prices are determined in futures exchanges, tea prices are established at auctions (located in tea-producing countries), which trade about one-third of global tea output. India has six auctions, but the two largest are in Colombo, Sri Lanka; and Mombasa, Kenya. Other producer-country auctions are held in Chittagong, Bangladesh; Jakarta, Indonesia; and Limbe, Malawi. The Colombo and Mombasa auctions trade tea mostly for export, and their prices (especially Mombasa’s) are considered the world price indicators.

Auctions in consumer countries, which operated during the 1970s and 1980s, have been less successful, with the exception of the London auction, once the world’s most influential. Until the early 1970s, London held the world’s dominant tea auction. London’s last auction took place on June 29, 1998, bringing to a close a 319-year-old tradition. Tea auctions had been held in London since the East India Company’s first auction in 1679. Aside from brief interruptions during the war years, auctions had been held at least once a week since 1864.

Kenya’s tea auction system began in November 1956 in Nairobi under the auspices of the East African Tea Trade Association. It initially traded small quantities of secondary-grade teas, but following increased interest from producers and buyers the auction moved to Mombasa in 1969 and started trading main grades of tea. A turning point for the Mombasa auction came on October 26, 1992, when, following relaxation of foreign-exchange controls, transactions began taking place in U.S. dollars. With other major tea auctions trading in local currency (including the one in London), this change probably accounts for Mombasa’s position as the world’s dominant tea auction.

The global tea market is not subject to the types of trade impediments faced by other commodity markets (e.g., cotton). Furthermore, unlike the markets for commodities such as cocoa, coffee, and rubber, there has been no United Nations–backed international price stabilization scheme in the tea market in the post–World War II (1939–1945) period. There have been two voluntary supply-restriction schemes (Wickizer 1951). The first, running from 1920 to 1921, grew out of the sharp price decline of 1920 and was led by India and Sri Lanka (then Ceylon). A second restriction went into effect in 1930, led by the same countries and for the same reason. A five-year International Tea Agreement was launched in April 1933 to support tea prices through export quotas, backed by India, Indonesia, and Sri Lanka. The agreement occurred in response to the collapse of tea prices during the Great Depression—they declined by 70 percent between 1927 and 1932 (Sarkar 1972).

**THE OUTLOOK**

Because most tea is consumed in low- and middle-income countries, the long-term outlook for tea depends mostly on income growth in these countries. The UN Food and Agriculture Organization (FAO 2001), for example, estimated that the growth in global tea demand for the 2000–2010 decade is unlikely to exceed 1 percent, which is close to the rate of demand growth during the 1990s. Most demand growth is expected to come from increased...
Teacher Expectations

Can the academic expectations that teachers develop for their students become self-fulfilling prophecies? Can predictions made about another individual actually cause outcomes that confirm the original prophecy, and if so, how and under what conditions? This question has generated considerable research as well as controversy in the social sciences. The volatile nature of the inquiry stems from the special obligation inherent in teaching. As with the healing professions, teachers are given the responsibility and held accountable to promote positive changes in their charges. If teacher prophecies about differential capability among students could explain the observed achievement gap between groups of students (a gap that disadvantages poor and ethnic minority children), this social-influence process carries large societal implications.

The expectancy concept and its potential for confirmation have a long history in literature and social science, beyond education. Categorization of people, settings, and events reduces the complexity of social stimulation. It enables people to quickly sort experiences, identify essential features, predict outcomes, and plan actions. Although categorization can provide clarity, it can also blind a person when faulty or stereotyped beliefs, either positive or negative, are applied. An example of positive expectancy effects is found in the ancient Greco-Roman myth about the sculptor Pygmalion whose love for the statue Galatea brought her to life. Reference to negative expectancy effects is found in a 1948 paper by the sociologist Robert K. Merton, who coined the term self-fulfilling prophecy. Using the bank failures of the economic depression as one example, Merton defined the component parts as “a false definition of the situation evoking a new behavior which makes the original false conception come true” (p. 195).

In Pygmalion in the Classroom (1968), the psychologist Robert Rosenthal and the elementary school principal Lenore Jacobson conducted the first experimental test of a positive self-fulfilling prophecy. Teachers were given false test information about a randomly selected group of children who were labeled intellectual bloomers and expected to show greater growth in their learning. At the end of the year, the children identified as bloomers outperformed other children on intelligence tests—an effect documented in the early grades. This study fueled controversy over methodological problems, numerous experimental replications, and interest in the investigation of naturally occurring expectations in classrooms.

Evidence supports a causal connection between teacher expectations and student achievement, although the debate continues regarding the magnitude of the effect. The expectancy effect is more powerful under certain conditions, with the factors that moderate the effect under study (Brophy 1998; Rosenthal 2003; Weinstein 2002). The causal model proves complex, highlighting differences in susceptibility of both teachers and students to such effects and the magnifying role of the developmental stage of the children as well as of contextual features. There exists potential for teacher perceptual confirmation regardless of student behavioral confirmation and for student disconfirmation of negative or even positive teacher expectations.

Other vital questions include the mechanisms by which expectations can exert effects on student achievement, the factors that shape the formation of academic expectations and for whom, and the methods by which negative self-fulfilling prophecies might be reduced. Many social science fields have explored teacher expectations and expectancy effects, using varied methods at multiple levels of analysis.

BIBLIOGRAPHY

Studies have documented that teachers treat high- and low-expectancy students differently, favoring highs with greater opportunity to learn and more positive interactions (Brophy 1998). Even young children are aware of differential treatment by teachers, which communicates information about the relative smartness of students in the classroom (Weinstein 2002). Thus, the mechanisms that bring about expectancy effects include the opportunity structure provided students, which directly impacts achievement, and ability messages, which through their shaping of student self-view and motivation to learn, ultimately impact achievement. Studies have also shown that differential expectations and differential treatment are expressed not only toward individual students but also toward groups of students—members of ability-based instructional groups within classrooms, academic tracks within schools, or high-poverty schools. Further, expectancy communication is evident not only in interpersonal interactions but also in the culture of classrooms and schools, where ability differences may be made publicly salient and instructional differentiation, such as a less rigorous curriculum for some students, may be a pervasive reality.

There also exists evidence of teacher bias in the formation of expectations—less clear with regard to gender, but more apparent in the stereotype-based underestimation of the ability of low-income, ethnic and linguistic minority, and special needs children. There is debate about the accuracy of teacher expectations, when judged against achievement scores, and the appropriateness of differentiated treatment. While it can be argued that expectations may play a larger self-maintaining role than self-fulfilling role, this debate also raises the question about the purpose for education—that is, whether a society is obligated to reach higher for all students.

Far less research has focused on how to reduce the occurrence of negative self-filling prophecies in schooling. Intervention approaches have included increasing teacher awareness of biased expectations and promoting equitable interactions with students, statewide reform efforts to alter multilayered components of a negative expectancy climate, and policy mandates to raise academic standards (expectations) and reduce the achievement gap. Multidisciplinary research on this social-influence process has demonstrated the limits of behavioral and social-cognitive explanatory models and the importance of systemic and ecological approaches. When schools are structured to sort students for differential opportunities rather than for the development of talent in all students, expectancy processes no longer lie simply in the minds of teachers but rather are fueled by educational policy.

**TEACHER-CHILD RELATIONSHIPS**

Attachment theorist John Bowlby (1969) argued that self-concept and understanding of relationships are determined, in part, by experiences in early relationships with caregivers, particularly parents. The nature and quality of these relationships are important, specifically the degree to which caregivers are available and responsive to children’s needs. Although children’s first significant relationships are typically formed with parents, alternative relationships formed with teachers and other primary caregivers are also critical to child and adolescent development. In fact, a national survey of adolescents (Resnick et al. 1997) revealed that the single most common factor associated with positive youth outcomes was a supportive relationship with an adult, and teachers were among the adults most frequently mentioned as the source of this support. The following sections provide a brief overview of what teacher-child relationships look like, the factors associated with the quality of these relationships, and the importance of teacher-child relationships in promoting children’s academic and socio-emotional competencies.

**WHAT IS A TEACHER-CHILD RELATIONSHIP?**

As children enter school, teachers play an important role in shaping children’s experiences outside of the home environment and early on can assist in supporting young children’s adaptation to new challenges and demands during the transition into a classroom environment. Aside
Teacher-Child Relationships

from their formal role of teaching academic skills, teachers are often responsible for regulating activity level, communication, and contact with peers (Howes and Hamilton 1993; Howes, Matheson, and Hamilton 1994; Pianta 1997). Teachers also provide behavioral support and teach coping skills (Doll 1996). In contrast to parent-child relationships, relationships between teachers and children are more likely to be time-limited in nature. Yet, teacher-child relationships are deemed important by children of all ages (Pianta, Hamre, and Stuhlman 2001) and are associated with later academic and social functioning (Hamre and Pianta 2001).

Teachers’ perceptions of their relationships with children typically are shaped by the level of conflict or closeness—that is, the degree of discord or warmth within a relationship (Ladd and Burgess 1999; Pianta 1994; Pianta and Steinberg 1992). Similarly, children’s perceptions revolve around the degree of emotional closeness and support, or negativity, within relationships with teachers (Bracken and Crain 1994; Ryan, Stiller, and Lynch 1994; Wentzel 1996). These perceptions of teacher-child relationships also appear to be consistent with observations of teachers and children interacting in the classroom (Howes et al. 1994; Pianta et al. 1997).

FACTORS THAT INFLUENCE TEACHER-CHILD RELATIONSHIPS

Research clearly indicates that the quality of teacher-child relationships is influenced by unique characteristics and previous relational experiences that both teachers and children bring to the classroom. Teacher-child relationships are frequently affected by children’s behavioral problems, though there are some important gender differences. Teachers often characterize their relationships with female students as closer and less conflictual than their relationships with male students (Bracken and Crain 1994; Hamre and Pianta 2001; Ladd, Birch, and Buhs 1999; Ryan et al. 1994), which may be related to the fact that boys more frequently display antisocial behaviors, such as verbal and physical aggression. Several studies suggest that children’s academic and socio-emotional competencies, or lack thereof, are linked to the quality of their relationships with teachers (Ladd, Birch, and Buhs 1999; Murray and Greenberg 2000). One report showed that teachers are most likely to report conflictual relationships with children whom they also view as having significant problem behaviors.

Several studies support the idea that teacher beliefs, experiences, and expectations also contribute to the quality of teacher-child relationships (Pianta, Hamre, and Stuhlman 2001). For instance, one report shows that teachers who report feeling depressed and unable to influence the development of children in their classrooms, and who are observed to offer less emotional support, are more likely to report significant teacher-child conflict, even in the absence of reports of problem behaviors.

The race or ethnicity of both teachers and children also seems to play some role in determining teachers’ perceptions of the quality of teacher-child relationships, though the evidence supporting this view is far from conclusive. In particular, an ethnic or racial match between child and teacher may be influential in the formation of positive, less conflictual relationships (Hall and Bracken 1996; Ladd, Birch, and Buhs 1999; Saft and Pianta 2000). Although teacher-child relationships are to some degree a function of characteristics of and interactions between individuals, it is important to recognize that they also have their own identity apart from specific, individual characteristics and interactions (Sroufe 1989).

IMPORTANCE OF TEACHER-CHILD RELATIONSHIPS

Positive, trusting, and low-conflict relationships with teachers from preschool through high school are key contributors to children’s adjustment to their social and academic environment. Bridget Hamre and Robert Pianta (2001) report that teacher-child relationships in kindergarten are highly predictive of long-term educational outcomes (into middle school). Specifically, teacher-child conflict appears to be associated with negative feelings about school and school avoidance, lower levels of self-directedness and cooperation in the classroom, and poor academic outcomes (Birch and Ladd 1997). Additionally, teacher reports of relational conflict are related to increases in children’s problem behaviors and decreases in competence behaviors over time (Pianta, Steinberg, and Rollins 1995). In contrast, young children whose teacher-child relationships are characterized by closeness show greater levels of overall school adjustment (Birch and Ladd 1997; Pianta et al. 1995). Similarly, Kathryn Wentzel (1998) reports a correlation for middle school students between teacher support and interest in school and suggests that teacher-child relationships may be particularly predictive of classroom functioning during transition points, such as the move from elementary into middle school. Importantly, children at risk for academic and behavioral difficulties are particularly well served by positive teacher-child relationships (Pianta et al. 1995). In summary, supportive, reciprocal relationships with teachers influence child development in multiple fashions and serve to promote positive emotional and academic outcomes, while protecting children from a variety of potential educational and socio-emotional risks.

TEACHERS

Psychologists and other social scientists since the early twentieth century have been concerned with learning and effective teaching. A century ago, education in the United States was a troubled institution. School curricula were seen as outdated and irrelevant, teachers were often ill-
prepared, and students often displayed low levels of motivation. In light of these circumstances, social scientists began to investigate ways to improve the educational system. The move toward more progressive educational policies based on psychological research has continued to the present.

Early questions revolved around the nature of the classroom. That is, what were the relative merits of lectures, classroom discussions, and demonstrations and activities? When the move from prepared lectures to discussion took place, there was initial enthusiasm for discussions as fostering greater learning. Similarly, the introduction of demonstrations and activities engendered considerable enthusiasm. Unfortunately, the research on the different approaches has been inconclusive; students show an aptitude for learning across a wide variety of classroom formats.

Just as educators have tried to restructure classroom dynamics, they have engaged in a constant quest to adopt the latest technologies for their pedagogy. Teachers have made use of radio, television, and even the telephone for delivery of educational information. The adoption of the Internet in education continues the technological innovation. So far, however, different classroom formats and technologies have not led to systematic improvements in pedagogy. Each technology appears to have strengths, but widespread and generalized improvements in learning resist easy development.

One of the earliest, successful pedagogical innovations was the Personalized System of Instruction (PSI) developed by the psychologist Fred Keller (1899–1996). This approach was based on behavioral theory and featured self-pacing geared toward mastery of a task. Keller proposed including lectures and demonstrations only as vehicles of motivation, not as information delivery systems. Even though the approach was thoroughly grounded in behaviorism, Keller stressed the importance of the personal and social aspects of the learning situation.

Empirical research has documented PSI as an effective pedagogical approach. However, teachers never adopted it universally, even at the height of its popularity. Nonetheless, this system still has adherents who use it successfully.

Theories in cognitive psychology prevalent in the early twenty-first century highlight the idea that the creation of cognitive schemas enhances learning. Further, the use of so-called deep processing (e.g., self-reflective thought, integration of ideas, writing to learn) appears to benefit learners. One little-known, but promising, phenomenon that was rediscovered and applied to educational research in the late 1980s, the testing effect, is explicable in cognitive theory results. The act of taking a test can itself foster better retention than actually studying the material. The advantage of testing accrues when learners must generate answers and process multiple concepts in essay-type items. In contrast, recognition tests, such as those featuring multiple-choice items, and repetitive studying do not reliably lead to as complete learning.

The apparent advantage of repetitive studying is evident for tests taken immediately after studying, but this spurious advantage disappears with delayed testing. Theorists speculate that the immediate reinforcement associated with repeated exposure to material to be learned leads to misplaced feelings of confidence and mastery on the part of students. Further, the difficulty associated with generating answers on tests creates in the learner the impression that learning is incomplete and insufficient, even as it actually benefits the person. Researchers have suggested that learning is enhanced when students have to overcome difficulties. The paradox is that when students encounter such difficulties, it facilitates memory for the material but results in the subjective feeling of lack of progress toward the learning goal.

The fundament that unifies the various types of active learning is the creation of a network of interrelated ideas. In the early twenty-first century, cognitive and learning theory takes it as an article of faith that a cognitive schema provides interconnections among related information, a structure that facilitates assimilation of new information and effective retrieval of already-learned material.

**ACTIVE LEARNING**

Psychologists and educators have adopted the principles of active learning as critical components of classes. Historically, demonstrations by a teacher that illustrated a particular phenomenon constituted the approach to active learning, even though it may have been only the teacher who was active. Engagement on the part of the students is the concept of active learning that prevails in the early twenty-first century, and it can take a variety of forms. Some common types of active learning include writing to learn, cooperative learning, interteaching, and just-in-time teaching.

In writing to learn, the main purpose is not communication; rather, it is learning. Writing about a topic enables a student to ruminate on the ideas and to synthesize information, thereby solidifying learning. When students engage in low-stakes writing, a teacher does not assess the content or the style. The focus is on the development of ideas. Subsequently, high-stakes writing can be a means of assessing the quality of the writing and the knowledge of ideas. In theory, writing to learn involves students’ evaluating ideas and information, which presumably helps them develop schemas and networks of interrelated ideas.
Cooperative learning involves the creation of a social setting to foster knowledge acquisition and retention. Educators have developed several different variations. The actual classroom process may differ significantly across the different types of cooperative learning. Empirical research has revealed a consistent, sometimes large, effect for cooperative learning compared to either competitive learning or individualistic learning. Investigators have documented the advantages of cooperative learning at all academic levels.

In cooperative learning, several students work together, taking responsibility not only for their own learning but also for that of the other group members. The critical components of cooperative learning include shared responsibility so that all members of the group learn, individual accountability for progress toward learning, face-to-face interaction, development of interpersonal skills, and self-monitoring by the group. Thus, cooperative learning relies on elements of cognitive theory and social psychological theory of group processes.

A development originating in the early 2000s that has its origins in Keller’s PSI approach and involves structure, active learning, and cooperation is called Interteaching. Interteaching places the responsibility for learning largely on the student, rather than on the teacher disseminating information via a lecture. In this approach, the instructor provides questions to guide students in a focused activity, and students then review the material to be learned and discuss it with fellow students in small groups. Finally, the students can request that the teacher address questions they have regarding the material.

Interteaching, like its predecessors, may not introduce elements that do not already exist in the classroom. What it involves is a rearrangement of behaviors and a redistribution of time devoted to individual and group work, discussion, lecturing, and out-of-class preparation. Like the other types of active learning, interteaching draws on cognitive theory but relies on a significant element of behavioral theory in its application.

Just-in-time teaching (JiTT), whose conceptual basis developed in the 1960s but was made practical through computer technology in the 1990s, involves student learning combined with the use of the Internet. Students take responsibility for learning specified material and for recognizing what aspects of that material they do not understand. JiTT relies on students to begin learning the material before class. Then the student communicates uncertainties to the teacher shortly before class time so the teacher can use class time most effectively to address the weaknesses in student learning. Class can be oriented toward what students do not know. Ideally, JiTT also engenders a spirit of cooperation between the students and the teacher.

TECHNOLOGY
Psychologists are often on the forefront of adopting new teaching technologies. The Internet and presentation software have become staples of the contemporary classroom. Preliminary evidence suggests that computer-based teaching can lead to greater learning than standard lectures when multimedia presentations are constructed so that the different components of a presentation are pedagogically integrated. The presence of excessive sound and graphics can lead to cognitive overload and reduced learning.

Theorists have speculated that multimedia presentations can enhance learning because the presentations foster multiple dual coding, that is, a combination of visual and verbal learning. This approach can increase student motivation while helping students encode concepts.

Presentation software can produce increased learning, but it has received criticism as being essentially a static medium that reduces teacher creativity and flexibility in the classroom. Some educators have responded to this criticism by noting that the software itself is not the problem; rather, the use of the software can be problematic if it does not lead students to process the material deeply.

Historically, new technologies have emerged and have become widely used in the classroom. Initial research often supports the efficacy of the new approaches, but sometimes it is not clear whether the increased student achievement stems from the new technology or from the additional enthusiasm of the teacher for the innovation.

TECHNICAL CHANGE
SEE Change, Technological.

TECHNOCRACY
Initially and most generally, a technocracy was a form of organizational structure or system of governance in which decision makers were selected on the basis of technological knowledge. In the past, such individuals were called technocrats, a term used frequently in the twenty-first century by, for example, journalists, but differently, to refer to individuals exercising governmental authority because of their knowledge rather than political profile (e.g., “a government of technocrats, not politicians”). When used in the twenty-first century, the term technocracy is more likely to mean governance exercised by technological systems themselves than by experts.

Sharing connotations with theocracy (government by a divinity or its representatives), autocracy (ruleless governance by a lone individual), and bureaucracy (governance via routinized exercise of authority by humans), technocracy contrasts with democracy, rule by the citizenry. In addition to having a high estimation of applications of science-based learning, advocates of technocracy (such as the engineer/social activist Howard Scott) view governmentality as problematic, the complexity of technological systems being itself an important contributor of difficulty. They believe that, where possible, decisions should be designed into systems, because direct application is most effective and efficient. If humans have to be involved in governance, they should be highly familiar with the systems, rather than those with the authority of office, divinely inspired, with charisma, or by the people at large.

Late twentieth-century social studies of technoscience (such as those of the scholar Bruno Latour) tried to broaden the notion of technology, applying the term to any routinized complex of artifacts, agents, and practices. Users of technocracy generally think of technology in a more restricted sense, as the highly complex systems distinctive feature of “high tech” social formations.

In 1919 the American engineer W. H. Smith claimed to have coined the term technocracy, but Scott, founder of the arguably fascistic social movement Technocracy, Inc., asserted that he had heard the term as early as the 1880s. Used explicitly in this period by diverse Progressive political movements in the United States, technocracy was presumed to be a natural and inevitable consequence of social evolution. Society was dependent on increasingly ubiquitous complex systems—like the railroad, those providing clean water, or those promoting public health—that themselves needed public support to function. Because systems were best understood by experts, technological expertise came to be seen as essential. The social chaos of the Great Depression of the 1930s exacerbated the perceived democracy crisis following from immigrant access to a broadened franchise. Giving governance to those who best understood technology (initially, engineers, such as Thorstein Veblen and Scott), but, later, managers (including James Burnham) would naturally promote scientific governance. Consonant with the positive social sciences, especially political science, technocracy also drew heavily on Western Utopian traditions (as in the work of novelist Harold Loeb) and a long American tradition of technological determinism.

A second period of the concept’s popularity came with the 1960s rise of postindustrial theorizing, which fostered talk of an “information society” based in knowledge rather than manufacturing. For Daniel Bell, author of The Coming of Post Industrial Society (1973) technocracy was marked by the increasing power of professionals, as a consequence of which society was taking a more self-conscious, planned trajectory. The chief legacy of this second wave period, however, is that technocracy has come to mostly be used critically, to acknowledge an unfortunate necessity, not to be advocated. In his book Autonomous Technology (1977), for example, Langdon Winner developed an “alternative conception of technocracy,” by adding “reverse adaptation” to the earlier technological imperative. Via technocracy, technologies have become ends, not means, displacing even the experts: “….It matters little who in specific obeys the imperative or enacts the adaptation” (p. 258).

With today’s widely shared sense that any human agency is marginalized by technology, technocracy is arguably common sense, even though its negative connotations mean only the critical freely use the term itself. Still, advocates of new systems feel compelled to justify them as democratic. Even though computing’s implications for democracy, as in many other social arenas, are contradictory, the democratic implications of automated information and communications technologies (AICTs) were the ones that were stressed. Indeed, if networked, digitized representations at least theoretically democratize access to knowledge, and on-line plebiscites can extend opportunities for direct democracy, their disintermediation lessening the need for representation.

However, increasingly ubiquitous, self-governing smart machines, having artificial intelligence, can govern affairs autonomously, thus decreasing any need for
democracy. Similarly, a perceived technology-enabled, rapidly proceeding globalization seems to lessen the need for any state.

Is computing the triumph of technocracy? This may depend on the ultimate cultural correlates of the new governance model emerging in cyberspace. This model takes institutional form in entities like the Internet Society and the World Wide Web Consortium, as well as in Free/Libre and Open Source Software development networks. Here governance focuses on devising technical standards, decisions about which are made whenever possible by consensus. Ostensibly democratic, such activities are open to the participation, either physical or electronically mediated, of anyone, as long as the participant can demonstrate the requisite technical expertise.

Perception of the technocratic affordances of new technologies has also spawned forms of resistance. As described by Richard Sclove in *Democracy and Technology* (1995) and especially in Scandinavia, AICTs are themselves used to support democratic technology consensus conferences, which aim to achieve broad social agreement before mega-projects begin. In these, cross-sections of the populace are encouraged to draw on their own experience, supplemented by expert responses to the citizens’ own questions, to develop independent positions with regard to proposed technological ventures.

As argued by cyberspace ethnographers like David Hakken, technocratic presumptions filter what “impacts” are seen as likely to follow from AICTs. The same presumptions interfere with seeing how social factors shape the technologies themselves. The increased centrality of technological systems to the reproduction of capital is one of several important factors promoting the building of technocracy into computerized life. Still, as the success of consensus conferences show, this tendency can be contested. It must be for democracy to be more than mere posturing. Once implementation begins, the broader social correlates of using complex technological systems can be very hard to reverse. To avoid technocracy, it is essential to insert democratic participation early in the design of complex technological systems.

**TECHNOCRAT**

A technocrat, according to the most basic meaning of the word, is someone who advocates or governs a technocracy—the rule of technical experts. The roots of the word *technocrat* lie in the classical Greek words for “skill” or “craft” (*techne*) and “rule” (*kratos*). The word *technocrat* is typically used to convey derogatory or ironic attitudes about technology and about the authority or power of those who understand and use technologies. Thus a technocrat is one who advocates technological or technical, rather than political, solutions to collective problems and who fails to consider the humanistic, historical, symbolic, moral, or personal elements of collective decisions. In France, for example, the word *technocrate* ("technocrat") is used by both the political left and right as an epithet for one who is said to administer or manage an organization on the basis of narrow technical expertise, and who lacks class consciousness, democratic commitments, moral conscience, and basic humanity (for example, Hecht 1998).

Daryush Sheyagan in *Cultural Schizophrenia* (1992) characterizes technocrats as “the managers of the technical, political, economic and scientific spheres of a modern society. They … take on the depersonalized, neutral quality of the world for whose efficiency they are responsible. They symbolize pure function stripped of all personal connotations … they are indifferent to the ethical purposes of what is produced” and can serve one type of political regime as well as another (pp. 148–149). However, if, as Jacques Ellul (1964) and Langdon Winner (1977) have suggested, technology is autonomous and technological imperatives determine decision outcomes, then in principle technocracy would not involve the authority of technocrats, for the real sources of authority and power would be impersonal and systemic.

Unlike the term *bureaucrat*, which since introduced by Max Weber has had a well-established place in the conceptual vocabulary and research of the social sciences, *technocrat* has had little use in social science research. Moreover, while a technocrat may also be a bureaucrat, *technocrat* can refer more generally to anyone who exercises scientific, technological, economic, administrative, or environmental authority.

The term is also used to refer to a member of a movement or organization that advocates governance by engineers or other technically trained experts instead of by...
politicians. Since 1933 in the United States, Technocracy, Inc. has been the principal research and educational organization representing the technocracy movement. Its predecessor, the Technical Alliance, was founded in 1919 by Howard Scott (1890–1970), who had been inspired by the writings of Thorstein Veblen (1857–1929). The official publication of Technocracy, Inc. is *North American Technocrat*. Henry Elsner Jr. (1967) has traced much of the history of the technocratic movement in the United States.

TECHNOLOGICAL PROGRESS, ECONOMIC GROWTH

Technological progress is the fundamental force underlying the long run rise in real income per person. Technological progress reflects the growth of human knowledge, from advances in basic science such as the discovery of the laws of thermodynamics to highly practical and applicable ideas regarding production, like the design of an airplane wing or the mechanization of repeated actions or management and workplace organization, like double-entry accounting, just-in-time production, and the techniques of modern inventory management. It is nearly impossible to overstate the role of technology in economic life. Imagine, for example, how one's life would be different without such everyday inventions as computers and telephones, anesthesia and antibiotics, automobiles and airplanes, and electricity and petrochemicals.

Economic growth occurs because individuals have either more resources at their disposal or better ideas for turning resources into goods and services. Increases in resources alone cannot drive persistent economic growth. Natural resources are limited in a finite world, and while education can dramatically increase the productivity of human resources, such gains are constrained by human lifespans. Countries have doubled the education of their workforce, going from five years of schooling to ten, but it is hard to imagine repeating this accomplishment. The gains available from mechanization are also limited. If industry increases the number of machines per worker, growth will slow as each machine adds less to output than the one before. Indeed, estimates pioneered by Nobel laureate Robert Solow attribute less than half of U.S. economic growth to increases in resources. The lion's share of growth stems from technical progress.

In addition to playing a central role in persistently rising income levels, the advance of scientific and technical knowledge have driven a number of important economic trends. In production, technological progress has been the primary force underlying the shifts from manual to mechanized production methods, from natural to synthetic materials, from human and animal to mineral sources of power, and from raw labor to highly educated and specialized workers. The adoption of new technologies often drives the expansion of markets. Larger markets are required to allow workers and firms to concentrate on highly specialized activities and increase the return to innovations that involve investments in specialized knowledge or machinery. Innovations in transportation and communication have induced correspondingly dramatic changes in the organization of economic activity, shifting production out of the home, raising the average size of business enterprises, concentrating production in cities, and...
increasing the geographic extent of trade and the role of international transactions in local and national economies.

**SOURCES OF TECHNOLOGICAL PROGRESS**

The Industrial Revolution, which marks the beginning of a unique economic era of persistent increases in per capita incomes, is inextricably linked to the scientific revolution, and the world’s current economic prosperity is difficult to imagine in the absence of fundamental advances in knowledge of biology, physics, and chemistry. Not all new technologies come from the scientific community, however. Private firms devote tremendous resources to applied research and development. In addition, many economically valuable ideas are the result of practical experimentation and the gradual accumulation of production experience. Even such high profile “inventions” as the Fulton steam engine—the mobile power source of the Industrial Revolution—drew on more than one hundred years of incremental improvements on earlier designs.

Unlike a hammer or a tractor, an idea can be used by many people at the same time. Indeed, because commercial success tends to attract attention, good ideas usually are hard to conceal. Once Henry Ford demonstrated that inexpensive cars could be mass produced on assembly lines, his production methods were widely copied. While early gains from an idea go to the inventor, as an idea spreads throughout an industry competitive pressure drives down prices, creating gains for society at large. Indeed, attempts to make use of the constant stream of new ideas generated by their competitors plays an important role in the tendency of firms in a given industry to locate close to each other, forming industrial clusters like Silicone Valley, Wall Street, and Hollywood.

Scientific research often generates insights that are valuable in many lines of business. Because of this, basic research is supported with public funds and new discoveries are widely disseminated. In more narrow and applied areas of knowledge, research is supported through the protection of intellectual property rights. These grant inventors a temporary monopoly on the use of their ideas, allowing them to recoup their research expenditures. Intellectual property rights attempt to balance the desire to reward successful research with the social benefits that derive from competitive markets and the widespread adoption of good ideas. In the pharmaceutical industry, drug prices typically fall by around 80 percent when a patent expires.

In addition to intellectual property rights, an educated workforce is essential to successful public and private research. Perhaps less obvious is the role of international trade. Access to large markets allows firms to spread the fixed cost of inventing a new idea thinly over a large number of units of output, raising the return to resources devoted to research. It is probably no accident that at the time of its Industrial Revolution, England had both the only European system of intellectual property rights and, due to an extensive network of roadways and canals, the most integrated national market in Europe.

**INTERNATIONAL TECHNOLOGICAL TRANSFERS AND ECONOMIC DEVELOPMENT**

For countries that are not on the technological frontier, technological progress owes more to imitation than innovation. Late industrializers—from the United States in the nineteenth century to China and India in the twenty-first—have always borrowed from the technological leaders of their day. The persistence of dramatic international disparities in income levels, however, testifies to the fact that successfully adopting existing technologies is neither easy nor automatic. Many technologies need to be adapted to fit local conditions including labor force skills, regulatory environment, availability of vital resources, and cultural differences.

Openness to international markets and an efficient legal system that protects the rights of foreign investors play important roles in attracting multinational companies that employ advanced technologies. Many developing countries, including China and India, have seen a marked increase in their growth rates directly following opening to international trade and foreign investment. On the other hand, international trade may lead developing countries to specialize in less technologically dynamic economic activities, such as agriculture and mining, and foreign investment in these areas may do little to promote ongoing technological transfers.

Because the introduction of a new technology generally creates both winners and losers, international technology transfers may also face deliberate and well-organized opposition. New technologies are often opposed by industrial elites that fear the loss of leadership to a new industrial class, by existing industries that are invested in older technologies, and by labor unions who fear the loss of jobs.

**MANAGING THE CHALLENGES OF TECHNOLOGICAL PROGRESS**

While technological progress raises average incomes over the long run, the costs and benefits of new technology are generally unevenly spread, creating a number of challenges for countries experiencing rapid technological progress. The introduction of new goods and processes often competes directly with established economic firms, causing them to adapt or be driven out of business, a process termed creative destruction by economist Joseph Schumpeter. The rise of the personal computer in the
1980s provoked a serious crisis at IBM, the leading maker of mainframe computers.

Technologies that raise output per worker are labor-saving by definition. Since the end of the Civil War (1861–1865), ongoing technical progress has reduced the share of agriculture in U.S. employment from 50 percent to less than 2 percent, and a similar process is currently underway in manufacturing. This release of labor from agriculture to other sectors has been an important force in rising U.S. living standards, but these large sectoral shifts have been a painful process for those directly involved.

Because the costs and gains from technical progress are unevenly shared, periods of rapid technical progress often see dramatic increases in income inequality such as characterized the European countries during their Industrial Revolutions. Because they were better able to adapt to the challenges of the computer revolution, educated workers have seen their wages rise quickly while other workers’ wages have stagnated.

In addition to managing the labor market turbulence and larger sectoral shifts brought about by technological progress, technologically dynamic economies may face a host of unanticipated challenges that call for innovative economic, legal, and regulatory responses. The spread of the automobile gave rise to the suburbs and fundamentally altered American cities. The development of household appliances reduced the time required for routine housework, contributing to the rise in female labor force participation and changes in family structure. Advances in information technology may require new regulatory and legal responses to protect intellectual property rights in media, deter identity theft, and cope with the challenges of increased global competition.

These are nontrivial challenges, but technological progress has also provided the world with a greater capacity to meet them. Industrialization has provided both industrial pollution and the means to manage it, and the economic surplus created by increasing output per person has provided management with the ability to support and retrain workers who lose their jobs to technical progress. As in the realm of technology itself, the ability to meet the challenges raised by ongoing technological progress is limited ultimately by human creativity itself.

TECHNOLOGICAL PROGRESS, SKILL BIAS

This entry will discuss the different approaches to total factor productivity measurement and define skill-biased technical change. Let $t$ denote a technology index and $x$ and $y$ denote inputs and output, respectively. Then the production function can be written as

$$ y = f(x, t). $$

*Technological change* is then defined as a change in the technology index $t$ that affects the relationship between inputs $x$ and output $y$. Given a change in $t$ (say from $t_1$ to $t_2$), technological change is said to take place if

$$ \frac{\partial f(x, t)}{\partial t} \neq 0. $$

Assuming that $t_2 > t_1$, technological change is called *technological progress* if

$$ \frac{\partial f(x, t)}{\partial t} > 0, $$

that is, if technological change allows the production of more output $y$ with the same quantity of inputs $x$. Alternatively, technological change is called *technological regress* if

$$ \frac{\partial f(x, t)}{\partial t} < 0. $$

Technological progress is usually measured in terms of the rate of technological progress

$$ \frac{\partial \ln f(x, t)}{\partial t}. $$

(1)

Under the assumption of constant returns to scale (which is the maintained assumption in this article), the rate of technological progress is also referred to as the *growth rate of total factor productivity* (TFP) or *total factor productivity growth*. 
There are four alternative approaches to the measurement of the rate of technological progress: growth accounting, the index number approach, the econometric approach, and the distance function approach.

The growth accounting approach to the measurement of the rate of technological progress was pioneered by Moses Abramovitz (1956) and Robert M. Solow (1957). It requires the specification of a neoclassical production function, \( y = f(x, \theta) \). Totally differentiating the production function with respect to \( t \) and rearranging yields the rate of technological progress

\[
\frac{\partial \ln f(x,t)}{\partial t} = \frac{d \ln y}{dt} - \sum_j \left( \frac{\partial \ln f(x,t)}{\partial x_j} \frac{dx_j}{dt} \right).
\]

As an example, consider the Cobb-Douglas production function \( Y = AK^\alpha L^{1-\alpha} \), where \( K \) is capital, \( L \) is labor, \( \alpha \) is the share of capital in output, and \( A \) is a measure of the current level of technology, referred to as total factor productivity. With this production function, equation (2) implies

\[
\frac{\dot{A}}{A} = \frac{\dot{Y}}{Y} \frac{\dot{K}}{K} - (1-\alpha) \frac{\dot{L}}{L},
\]

according to which the rate of growth of \( A \) is just the rate of technological progress (under constant returns to scale). Intuitively, \( \dot{A}/A \) is the growth in output that cannot be accounted for by growth in capital and labor and is often called the Solow residual, after Robert Solow, who suggested this method of estimating the rate of total factor productivity growth.

Pioneered by W. Erwin Diewert (1976), the index number approach is an extension of growth accounting (from a continuous-time framework to a discrete-time framework). Under the assumption of cost minimization and constant returns to scale, equation (2) can be rewritten as

\[
\frac{\partial \ln f(x,t)}{\partial t} = \text{Total factor productivity growth} = \ln (I_p) - \ln (I_x)
\]

where \( I_p \) is a (real) output quantity index and \( I_x \) an input quantity index. Equivalently,

\[
\text{Total factor productivity growth} = \frac{I_p}{I_x},
\]

according to which the rate of technological progress is a function of the ratio of an output quantity index to an input quantity index. Clearly, the index number approach does not require the specification of a production function, although we did use it above to establish the equivalency between the growth accounting approach and the index number approach.

The index number approach is widely used by the majority of statistical agencies that produce productivity statistics (see Diewert and Nakamura 2003 for details). One critical issue regarding this approach is the selection of the appropriate indexes. Statistical indexes are mainly characterized by their statistical properties. These properties were examined in great detail by Irving Fisher (1922) and serve as tests in assessing the quality of a particular statistical index. They have been named, after Fisher, as Fisher’s system of tests (see Eichhorn 1976 for a detailed analysis as well as a comprehensive bibliography of Fisher’s “test” or “axiomatic” approach to index numbers).

The econometric approach involves estimating the parameters of a production, cost, or profit function. With a production function, the rate of technological progress can be measured directly using equation (1). With a cost function, \( C(r, y, \theta) \), where \( r \) is the vector of input prices and the assumption of constant returns to scale, the rate of technological change can be shown to be

\[
\frac{\partial \ln f(x,t)}{\partial t} = \frac{\partial \ln C(r,y,t)}{\partial t},
\]

where \( \partial \ln C(r,y,\theta)/\partial t \) is the “dual rate of cost diminution.” With a profit function, \( \pi(r, y, \theta) \), and the assumption of constant returns to scale, the rate of technological progress can be shown to be the product of the dual rate of profit growth and the ratio of profit to revenue, as follows,

\[
\frac{\partial \ln f(x,t)}{\partial t} = \frac{\partial \ln \pi(r,y,t)}{\partial t} \times \frac{\pi(r,y,t)}{py},
\]

where \( p \) is the price of output. While the econometric approach provides deep insights into the production structure (i.e., the price elasticities as well as the elasticities of substitution), it assumes that the firms or industries in question are fully efficient (i.e., operating on the production frontier), which has been proved not to be the case by studies on technical and allocative efficiency.

Finally, the distance function approach to measuring total factor productivity, introduced separately by Ronald Shepard (1953) and Sten Malmquist (1953), seeks to separate total factor productivity into two components: changes resulting from a movement toward the production frontier and shifts in the frontier. Mathematically, the Malmquist total factor productivity index is given by

\[
m_o (y, y_{t+1}, x, x_{t+1}) = \frac{d^t+y_{t+1} (y, x_{t+1})}{d^t (y, x)} \times \left[ \frac{d^t+y_{t+1} (y_{t+1}, x_{t+1})}{d^t (y_{t+1}, x)} \times \frac{d^t+y_{t+1} (y, x)}{d^{t+1} (y, x)} \right],
\]
where the term outside the brackets on the right-hand side measures the change in relative efficiency between years \( t \) and \( t + 1 \) and the geometric mean of the two ratios inside the brackets measures the shift in technology (technological progress) between the two periods evaluated at \( x_t \) and \( x_{t+1} \). This approach has several advantages. It does not require a specific functional form, and it does not assume that firms are operating at their efficient level. However, implicit in the approach is the assumption that all units (firms, industries, or countries) being compared have the same production function, when in fact evidence suggests that even firms in the same industry do not have identical production functions.

In our discussion so far of the four approaches to the measurement of technological progress, we implicitly assumed that technological progress is factor-neutral in the sense that the marginal rate of substitution between any two inputs (measured along a ray through the origin) is not affected by technological progress. Studies, however, find that technological progress is not factor-neutral; rather, it is skill-biased. **Skill bias** occurs when a shift in the production function (technological change) favors skilled over unskilled labor by increasing its relative productivity and therefore its relative demand and skill premium.

**BIBLIOGRAPHY**

Apostolos Serletis

**TECHNOLOGY**

Technology refers to the underlying production methodology through which inputs or resources are converted into output (goods and services). At a point in time there is one best way to produce a good or service. In other words, there is a well-defined production technology at a point in time. Over time, the technology can change as better, more efficient, and cheaper means of production are invented. Such changes might be due to deliberate attempts by businesses and governments (called "endogenous technical change") or they may be accidental (due to serendipity). In the long term, new technologies build upon previous technologies to yield better, more refined products and process. In that context, it is widely argued that perhaps man’s greatest innovation was the wheel.

Sometimes technology is treated as another input in the production process, like labor or capital, and in other instances it is viewed as a catalyst that makes existing inputs more productive. Two unique features that set technology apart from other factors are that it has the potential to yield disproportionate returns for inventors, and there is uncertainty associated with the invention and use of new technology. Inventors are able to earn disproportionate returns when they have a unique product that confers a monopoly upon them. The uncertainty associated with technology might be related to the race to invent first, or it might be with respect to research resources necessary for innovation success, or with the potential audience (who will use the new technology and how fast?).

Some technologies improve the product processes (by making them more efficient and, consequently, cheaper), whereas others introduce entirely new products. The Internet has enabled process improvements in a number of instances (e.g., via online brokerages or online travel agencies), whereas a new pharmaceutical drug for an illness previously without a cure may be viewed as a product innovation. More fundamentally, process technologies affect production costs, whereas product innovations have the ability to create new markets.

The ingredients to new technology are the research and development (R&D) resources. These include scientists and engineers and related physical resources (research laboratories and so on). The output of R&D is generally measured in the number of patents granted. The number of patents, however, is an imperfect measure because it does not account for inventions that are not patented, and it treats patents of varying importance qualitatively the same.

The development of new technology can be seen as a process involving three distinct stages— invention, development, and diffusion. Invention involves the conception of a new idea about a new product or a new process.
Development refers to the building of a prototype and testing its usability, possible side effects, and longevity. Diffusion is the marketing stage, when the new technology is dispersed to the potential audience or users. Cooperation among private firms or between the public and private sectors can occur at one or all of these stages.

Some technologies are more flexible than others. Flexible technologies enable substitution among inputs; for example, grocery stores can employ a large number of checkout clerks and have relatively few (or no) automated checkout machines, or they can have few clerks and more automated machines. Inflexible technologies, on the other hand, do not permit substitution among inputs; for example, a cab company should have at least one driver for each cab to deliver viable service—two (or more) drivers and no cars are as useless as two (or more) cars and no drivers. Over time, however, improvements in technologies can alter the substitutability among inputs—think about what will happen to the car-driver substitutability as "smart" highways become a reality. Furthermore, there might be differences in the nature of technologies as production expands. In some cases there might be an equal bang for the buck as inputs are increased—that is, doubling of all inputs doubles output (technically called "constant returns to scale"); in other cases there might be less than (or more than) proportionate returns—that is, doubling of all inputs less than doubles output—decreasing returns to scale.

As the importance of technologies has come to the forefront, so has the attention of researchers on the process of technological change. One interesting aspect in this regard is the premature technological obsolescence. Joseph Schumpeter foresaw this many decades ago when he referred to this as the "gale of creative destruction" (Schumpeter 1950). In industries susceptible to rapid technological progress (e.g., the electronics industry), successful technologies might become prematurely obsolete as they are overtaken (or "leapfrogged") by newer technologies before full benefits have been realized. While this is somewhat of a concern, governments generally have tried to let the markets work by not blocking or delaying premature obsolescence.

Market competition can play a crucial role in the production and use of technologies. The Schumpeterian hypothesis posits that monopolies, due to their reserves from past profits, are perhaps better equipped than their competitive counterparts to deal with the uncertainties of research and innovation. However, competitive pressures might induce firms to seek out better production methods and new products, either through their own research or via licensing the technology of others. Some software companies choose to develop their own software, whereas others license some software from others. The empirical evidence regarding the role of competition and firm size is rather mixed. Many large competitive firms have been quite innovative (e.g., Canon, 3M), whereas small inventors have also contributed useful technologies. The classic example in this instance is the development of the Apple computer in a garage. Firms might cooperate in the development of technologies among themselves, or there might be cooperation between the public and private sectors. Some governments such as the U.S. government have relaxed laws to check anticompetitive practices to allow cooperation in research. These moves have led to the emergence of consortia to jointly engage in research in pursuit of new technologies.

A number of new technologies can have implications for workers as they tend to be capital-using and labor-saving. Examples of such technologies include online banking, which might affect the jobs of bank tellers, and online travel agencies, which threaten the jobs of travel agents.

Full benefits of technologies are realized when they are optimally diffused. The diffusion of technologies occurs over time, because in some instances users have to incur monetary and learning costs (consider a new type of software that requires the user to spend time to learn what the software can do). Governments sometimes subsidize these learning costs directly (e.g., with cash grants for adopting energy-saving building technologies) or indirectly (e.g., with free user-education clinics by agriculture extension services). The transfer of technologies might occur via legal or illegal means. Legal means include research joint ventures among firms pursuing new technologies or licensing agreements where firms authorize others to use their technologies for a fee. Sometimes, however, these licensing arrangements can have harmful effects when firms refuse to license complementary technologies. In such instances, the pace of technological change is somewhat slowed. Internationally, developing nations generally seek to adopt technologies from developed countries by inviting foreign investments. But developed nations often are reluctant to offer the latest technologies because the existence and enforcement of intellectual-property protection laws is typically lax in developing nations. In recent years international treaties have tried to bring various nations onto a somewhat equal footing in regards to the protection of intellectual property. Illegal transfer of technologies occurs when rival firms are able to copy or use technologies without approval. Such spillovers of technologies are partly driven by the nature of technology (some technologies are easier to copy than others). Common means of technology spillovers include industrial espionage, reverse engineering (unraveling a product or process to learn about its construction), and hiring scientists and engineers from the inventor firm. Governmental ability to check technology spillovers is limited by the nature of technologies and by
jurisdictional constraints. Government-sponsored technologies sometimes overcome these issues by making certain new technologies freely available in the public domain.

Often, choosing between alternate technologies can have long-term implications that can render some choices inefficient and very costly to alter over time. In other words, technological choice can have inertia when production processes are locked into specific technological streams. Two glaring examples of this are the keyboard settings of typewriters (and now computers) and the width of railroad tracks. The QWERTY settings of the manual typewriters were historically chosen so that the keys would be least likely to lock up, hence the choice, given the state of the technology at the time, was efficient. However, over time, the manual typewriters evolved into electric, then electronic, typewriters, and finally into computers. These iterations did not face the problem of keys locking, but the QWERTY format for keys has almost universally persisted, in spite of some alternate formulations that have been shown to be more efficient. In the other example, the choice of the width of rail tracks has implications for how far the rail network can ply and is very costly to change over time. Even today, a number of countries continue to have tracks of more than one width, creating networking problems within the country (these issues are even more pronounced in an intercountry setting). It seems, however, that governments have learned from past mistakes, and in some cases international standardization bodies (such as the one to manage the spread of the Internet) are being formed in early stages of technologies to avoid bottlenecks in the future.

Government involvement in the production, marketing (or diffusion), monitoring, and protection of technologies varies a great deal. Governments might need to monitor certain technologies for their effects. For example, in the United States new drugs have to undergo extensive testing for possible side effects and have to be approved by the Federal Drug Administration (FDA) before being made available publicly. Other technologies have to be tested for their effects on the environment. A key aspect of government technology policy deals with ensuring adequate returns to inventors (to preserve incentives for undertaking the risks of technology development) and creating conditions for long-term technological growth. Governments generally have policies to deal with intellectual-property protection and with subsidies to research. Patents that grant monopolies to inventors for a specific time period (currently twenty years for most patents in the United States) have proven quite popular despite their shortcomings. Patent applicants have to prove their own and the invention’s credentials (i.e., uniqueness of their invention and their priority of discovery). The underlying rationale behind patents is that they balance the costs of monopoly grants against the long-term benefits that are realized when the secret patent formulae become public knowledge at the time of patent expiry, spurring future innovations. In practice, there is an interesting difference between U.S. patent policy and how patents are granted in (most of) the rest of the world. The United States grants a patent to the first person (or institution) to invent a new product or process; this person might not be the first to file the patent application. Most other countries, however, award a patent to the first to file, who might not be the original inventor. Both systems have merits and shortcomings. The U.S. system follows the essence of how patents should be granted, but leads to costly and socially wasteful litigation, especially in instances where the social value of patents is rather small. The rest of the world system avoids costly litigation, but can result in grave injustices when original inventors are slow to file the paperwork.

In recent years, the Internet, or more generally, “soft” technologies, have generated an interesting set of issues both for market participants and for governments trying to regulate technologies. Unlike “hard” or physical technologies (e.g., a tractor or an airplane), soft technologies are difficult to monitor (protect) and easy to transfer. Which aspects of a new software are like a language (and thus cannot be protected), and which aspects are like commercial products (and thus can be protected)? Transmission of soft technologies also makes convenient the separation of production and marketing over large geographical areas and eliminates the use of middlemen or substantial transactions costs. For example, soft technologies such as computer software, music, and e-books can be produced in one corner of the world and marketed in another via the Internet without the need of a middleman. Governments in such instances are somewhat powerless to monitor (and tax) these transactions. In effect, innovations in instruments of regulation have failed to keep pace with the speed of technological change.

The United States has been the world leader in technology since the end of World War II (1939–1945). Many important inventions and discoveries originated in the United States, and a number of these were byproducts of the U.S. defense and space programs. In the early 1980s, however, there were some concerns about the United States’ declining technological leadership. It became evident that although many inventions were still originating in the United States, other countries were taking the lead in perfecting these technologies by making them more user-friendly. (For example, although the microwave oven was invented in the United States, there are hardly any domestic manufacturers of these ovens left.) These concerns prompted the U.S. government to strengthen intellectual-property protection in some cases and to stress better commercialization strategies for new technologies.
Two noteworthy developments in this regard were the provision of patents to semiconductor chips and the introduction of legislation that makes it easier for federally sponsored innovations to be commercialized. Universities in the United States are also now able to hold patents and benefit from commercialization of the technologies invented by their staff. It remains to be seen, however, how the world's technological leadership will evolve, especially with the advent of soft technologies that are difficult to control and not geographically constrained. Another key issue concerns the extent and speed of technological “trickle down” from developed nations to developing nations.

TECHNOLOGY, ADOPTION OF

The adoption of technology is represented in the popular imagination as a straightforward process whereby the best technology wins in the marketplace, satisfying consumer needs. However, this superficial understanding neglects a number of important issues that shape technological adoption and the mechanisms of the process itself.

TECHNOLOGY AND THE DIFFUSION MODEL

The classic representation of technology adoption is Everett M. Rogers’s technological diffusion curve, which he outlines in his 2003 book The Diffusion of Innovations. This s-shaped curve is broken up into three phases: innovation and early adoption, accelerating adoption, and saturation. In the first phase the technology is rare, unknown, and untested. First phase users are often very different from the general public or mass consumers, whether in their general interest in novelties and new gadgets, or their specific organizational or occupational needs. For example, “Segway” personal transporters are not moving into mass circulation as fast as their inventor might hope, but airports and others with the need for moving security personnel have adopted them more readily. Similarly, being the first to adopt a fax machine or a cell phone was a risky proposition at first: There was no one to communicate with and it was not clear that the technology would be successful. In accelerating adoption more broad markets for innovations emerge, and new groups of potential adopters engage the technology, which rapidly spreads. At saturation the rate of new adoption slows and the market for a new technology is relatively stable, although economic activities such as replacement, repair, and accessorization may be quite dynamic. The diffusion model of technology adoption is a very effective model for describing successful consumer products, and it originated in Rogers’s studies of the communication of new ideas.

The origin of the diffusion model in studies of the dissemination of ideas leads to weaknesses in the model. The first is a pro-diffusion bias that is part of the core language of the model. For example those who are hesitant to adopt new technologies are described as “laggards,” which positions them as irrationally risk-averse and resisting new technologies adopted by risk-taking “early adopters,” rather than as hesitant to expend scarce resources on an untested new product.

The second problem with diffusion as a model of new technologies is that it leaves the design process for technologies unexamined, as well as the organizational contexts of technology adoption. Bruno Latour found in his 1996 study that when discussing contemporary corporate settings in particular, the designers and inventors interact with many different social groups (which may or may not be end users), and the earliest “adopters” of a new technology are the financiers, designers, managers, and suppliers and manufacturers who must be “enrolled” into supplying the resources for bringing the technology to a point of relative stability and maturity before it can move into the market. Within this process, asserts Robert J. Thomas in his 1994 book What Machines Can’t Do: Politics and Technology in Industrial Enterprise, the organizational contexts of technology’s design and implementation are most important, and internal politics, relationships with suppliers, employment markets and expertise, and other factors shape design and implementation or non-adoption of new technologies.

This points to the final issue with the mainstream diffusionist models of technology adoption: the assumption that the technologies that are moving into the marketplace are somehow the “best” in some unambiguous technical sense. But “best” can only be defined in relation to a...
particularly group’s interests and activities. Any Apple™ user will argue that the near monopoly that Microsoft™ enjoys in the marketplace does not reflect that the “best” operating system has been adopted. Therefore, proposes Wiebe E. Bijker in his 1995 study, social and economic power dynamics shape the processes that produce new technologies to be adopted and defined as “working,” and the potential adoption patterns of those technologies across different user groups. Technology adoption discourses also assume that the technology is stable as a material and symbolic configuration: that there is closure of the technology. This assumption is not necessarily warranted: Sometimes in the process of the adoption a technology is adapted both materially changed, in terms of modifications or rebuilding, and certainly symbolically reconfigured, as the imagined and intended meanings and uses of the technology are reworked in different settings. In other cases, such as computers and cellular telephones, rapid changes in versions and models disrupt a smooth diffusion curve, as new features render technologies apparently obsolete, and closure and compatibility are not achieved.

TECHNOLOGY AND COMPATIBILITY

The issue of compatibility points to the complexity of the adoption of technology in varying social contexts. In all contexts of technology adoption, a new technology must fit within existing manufacturing and use infrastructures, meet perceived needs, be nominally affordable, and be convergent with important cultural ideals. Each of these five elements presents different barriers to adoption in diverse cultural, particularly international, contexts. A technically functional technology that disrupts important social processes or relies on scarce resources will not be adopted. This is part of the reason that patent offices are social processes or relies on scarce resources will not be adopted. This is part of the reason that patent offices are

TECHNOLOGY, CELLULAR

Japan developed the world’s first analog mobile phones in 1979. They spread rapidly, outstripping the world’s landline systems within fifteen years. By 2006 the majority of the citizens of Europe, North America, and the wealthier nations of Asia, Africa, the Caribbean, and Latin America owned mobile phones. The United Kingdom had more mobiles than people, and there were 207 million users in the United States. More than twenty manufacturers produced them, and most nations had converged on GSM transmission, which was designed for European compatibility, although it coexisted with CMDA and iDen standards in the United States, Australia, Japan, and South Korea.

Most innovations have come from Japan, where a dense population that commutes to work, a high-tech industry long focused on miniaturization, and conducive social and consumer relationships led to early adoptions of camera and video phones, GPS (global positioning systems), text messaging, Internet, and music player capabilities. In Japan third-generation (3G) systems were the norm by 2005. Europe, South Korea, Taiwan, and coastal China are said to lag behind Japan by eighteen months, and North America lags three years behind. Elsewhere, developing nations rejected landlines in favor of cheaper mobile systems. The rollout of 4G systems is anticipated in Japan around 2010.

Mobile phones are not without problems. Many studies confirm the higher risk of auto accidents while using mobiles, even hands-free systems. Some scientific evidence shows increases in cancerous tumors among heavy, long-time users. Transmission towers are unwelcome sights in residential areas. Mobiles are also used in identity theft and credit card crime, in the coordination of terrorist attacks, and as detonators for bombs. Due to possible radio-wave interference, their use is banned in airplanes, hospitals, and some high-tech facilities. Theft of mobiles is common, with black markets on the Internet and in major cities.

Despite their problems, mobile phones have changed human communication profoundly, freeing it from the ancient constraints of physical proximity and spatial immobility. They have been rapidly adopted across cultures, age groups, and literacy and income levels, though in polyvalent modes. Mobile use initially was similar to the use of pagers by doctors and business people. Later mobiles became status items, especially among teenagers, who engaged in a “personalization culture” that included the use of faceplates, hand cords, stickers, and ringtones. For adults, status shifted to broadband Internet access.

Mobiles have become a basic technology of emergency response. Drivers use them to report accidents,
police and fire departments use them as a back channel in disasters, and the elderly carry them “just in case.”

Australian studies show that high percentages of mobile users are “cellular Samaritans” who use their phones to summon help for those in difficulty. Camera and video phones allowed instant reporting on the 2005 Indian Ocean tsunami and Hurricane Katrina. Japanese users can even be informed of impending earthquakes.

Sociologists have noted across cultures, genders, and age groups an increase in “grooming calls,” by which members of a family or group show concern and “nearness.” These short, frequent calls reinforce bonds of affection. Immigrant families and diasporic clans in particular do this. However, the “universal availability” of mobile users also allows the reinforcement of hierarchy. Bosses call employees outside work hours, parents monitor children, and couples monitor each other: “If you are without a mobile phone it means that no one depends on you for urgent direction” (Bautsch et al. 2001, p. 3).

The location of mobile use is problematic. Mobiles have been banned from theaters, religious institutions, funerals, airplanes, and many restaurants, and their use is frowned upon in museums, bookstores, trains, and buses. A dynamic of “civil inattention” has arisen in which bystanders pretend to ignore mobile conversations and speakers use vague or euphemistic language. Mobiles are also used as symbolic bodyguards in public areas to ward off unwanted attention or to refuse to participate in public space: “Public space is no longer lived in all of its aspects, stimuli and prospects, but is kept in the background of an itinerant cellular intimacy” (Fortunati 2000, p. 11).

Receiving mobile calls is an area without norms. Phones may be on, off, or in message-only mode, as users determine their degree of availability. Users decide whom to give their numbers to, whom to block, whom to answer immediately, and who hears a busy signal. Finnish studies show that men are more likely than women to turn mobiles off to avoid social control. Because calls arrive unpredictably but habit dictates that they be answered, face-to-face conversations and other calls must be “suspended.” Such interruptions cause anxiety for both parties, leading to anomic and difficult restarts. Users must also manage facial expressions and body language for multiple audiences, indicating primary and secondary importance to those present and absent. Such “managed availability,” however, has increased the capacity of parents in particular to coordinate various roles. But managing role conflicts and the discrepant awareness of conversation partners may be difficult for older users, and may promote broad but shallow relationships among younger users.

One alternative is SMS (short message systems), or “text messaging.” SMS patterns tend to follow earlier pager use, though today’s users can communicate through emoticons or delay responses via timers. Finnish studies, however, show that feedback is expected within 15-30 minutes. In Asia SMS users tend to be young and to belong to linguistic subcultures, and they are often killing time in public places or transport. SMS offers friendship tryouts, invitations without risk, and the cost is shared by sender and receiver. Some Japanese teens maintain multiple personas for hundreds of meru tomo (email friends), and SMS is the common channel for arranging enjo kosai, or paid “dates,” between businessmen and high school girls.

The mobile’s impact on individuality is also an area of concern. Traditional feelings of longing, homesickness, sadness, or insecurity are assuaged by calls and thus leveled out. Mobiles diminish the number of true hellos and good-byes. Lost are reflective periods when people review past actions and plan future ones. This culture of “nomadic intimacy” may portend more peripheral relationships, but fewer deep ones (Fortunati 2000). The deregulation of social life is another implication. “Nights out [are] characterized by endless deferrals and reshuffling of meetings and events which might never occur,” writes Sadie Plant (2003, p. 64), and “freedom from punctuality is permitted by constant ability to update other parties as to your status” (Townsend 2000, p. 94). In Italy the popularity of the mobile “seems to be associated with its support for a spontaneous, disorganized lifestyle that has always reigned among most of the country’s population” (Geser 2004).

The mobile has also made covert information exchange more possible. Some critics call this gossip, but others see it as decentralizing or democratizing. Parents communicate with other parents about children’s attitudes and whereabouts; employees engage in a similar dynamic about bosses; and law officers speak to each other rather than through dispatchers or superiors. In China mobile networks have spread news censored by the government and allowed seemingly spontaneous demonstrations. But studies show that mothers and wives act as the mobile information hubs of most families, so although mobiles may reduce the number of shared family experiences, they seem to be assimilated to traditional roles.

In the future, as the distribution of antennas grows denser, the location of every mobile will be determinable by GPS. In Japan, location within 30 feet was the norm by 2006, whereas in the United States the few GPS-enabled systems were accurate to 300 feet. GPS will be standard in 4G systems and, combined with built-in compasses, will allow users to point phones at buildings to find addresses, businesses, and friends, as well as to navigate roads. One side effect may be a barrage of business advertising. Barcode scanners may also become standard on mobiles, so that consumers concerned about food safety and product origin can “source” their purchases on databases before buying. Pocket-sized mobiles with SIMs (subscriber iden-
tity modules) will serve as credit cards that can be passed over sensors, like RFID (radio frequency interface devices) tags (Kohiyama 2005). Because SIMs are removable, users may have different mobiles for different occasions; they may even use friends’ phones, because their SIM carries their rate plans and callers lists. Batteries may become universally available, recharged, or swapped cheaply at kiosks or vending machines. Increased demand for Internet uses will lead to multilayered rate plans, and SMS will prevail underground on trains and in subsurface rooms. South Korea has announced plans to send out traffic tickets, fines, and even indictments by SMS. All mobiles will connect to nearby workplace, school, or community LANs to make use of the Internet when possible. Future architectural designs will change, allowing for ubiquitous mobile phone niches. World cities such as Tokyo, New York, London, and Paris may consist of people whose work requires face-to-face proximity for deals and transactions, whereas mobiles will allow others to work nomadically.

TECHNOLOGY, TRANSFER OF

The first humans developed new and better ways of production, and those around them watched and imitated. When the new and better ways became more complex, then the innovator would often teach the innovations to others. Since the beginning the transfer of technology has followed innovation. Technology is transferred from parents to children, from masters to apprentices, from teachers to students, from managers to workers, and from workers to workers. Technology spreads both horizontally (to competitors) and vertically (to suppliers and buyers) from a given innovating firm. It even spreads to seemingly unrelated industries (consider the case of the transistor that was developed for hearing aids but ended up in radios, TVs, computers, and space crafts).

However, the origin of the term technology transfer and its study as a separate phenomenon can be traced to the massive gifts of technology from the United States to Europe and Japan immediately following World War II (1939–1945). Many U.S. firms freely opened their doors so that European companies could come and study their production processes. Blueprints and patents were freely shared.

During the cold war between the United States and the Union of Soviet Socialist Republics (USSR), both sides encouraged the transfer of their technology to lesser-developed countries in order to help the recipients develop and to win allies. It was assumed that economic development required acquisition of modern technology. During the 1950s and 1960s, international organizations (such as the United Nations’ Expanded Program of
Technical Assistance) and private foundations (such as the Ford and Rockefeller Foundations) were the primary conduits of international technological flows.

Many hoped that the farther a country lagged behind cutting-edge technology the more they would gain from acquiring that technology. Unfortunately this hope was misplaced. Experts discovered that countries closer to the technology frontier were better able to absorb cutting-edge technology than countries that lagged far behind. For example, countries needed reliable electricity before they could efficiently use any technology, such as computers, that was electrically driven. Furthermore, countries needed educated indigenous people who could understand both the new technology and the country’s special needs in order to modify the technology so that it could work efficiently in the new environment. In the late 1970s and 1980s, literature emerged on appropriate technology where appropriate usually meant small-scale, simpler, and often manually powered technology such as hand pumps instead of electrically driven pumps. However, this appropriate technology was not always well received because it was viewed as inferior to what the developed world used.

During the 1980s and 1990s, some hoped that multinational companies would somehow find a way of successfully taking the most advanced technologies to the poorest countries in order to get the greatest profits from closing the largest technological gaps (and from paying lower wages). Contrary to this hope, most multinationals did not set up operations in the poorest countries; instead, they set up subsidiaries in countries that were already clearly on the path to economic development. Furthermore, multinationals have a strong incentive to keep their technology from any competitors. Some of a multinational’s technology is expected to leak to competitors through migration of workers from multinational to domestically owned firms, through reverse engineering, or through industrial espionage. To minimize the risk of competitors acquiring their technology, many multinationals pay their workers significantly more than domestic firms pay (to keep workers from leaving) and do not give their best technologies to their foreign subsidiaries.

In the 1990s and early 2000s, a large literature emerged trying to estimate the relationship between foreign direct investment and growth rates of developing nations via technology spillovers. This literature assumes that technology naturally spills over the borders of a firm to neighboring firms and is plagued by problems with:

1. how to measure technology,
2. determining to what extent the foreign investment caused the growth or the growth attracted the foreign investment,
3. modeling and estimating the interaction between domestic development of technology and the foreign technology, and
4. explaining how and why the spillover effect occurs, especially because the firm has a strong profit motive to stop it.

The policy implication of many of these studies is that governments of lesser developed nations should actively encourage foreign direct investment. However, the problems listed above may invalidate that conclusion. Furthermore, this literature tends to consider only the positive effects of foreign direct investment and ignore potentially negative effects such as dependency, loss of sovereignty, increased corruption, disruption of native culture, and risk of capital flight, which can cause financial crises such as the one that swept Asia in 1997–1998.

TECHNOLOGY, VIDEO

Video technology was developed as an adjunct to centralized television systems. Its widespread adoption since the 1970s has had the profound impact of integrating film and television culture into global everyday life. Initially many hoped that video technology would lead to greater diversity of programming and an expansion of television’s function beyond ephemeral entertainment and would empower the ordinary viewer. The empowerment that has occurred has increased cultural fragmentation and an isolation of viewers from each other. Thus video technology contributes to the general post-1970s trend of privatizing life spheres.

Video is not a precise term. It most commonly refers to those technologies that record or download electronic images, but the general reference to all electronic images
remains. In analog systems the recording is achieved by breaking down reflected light into a series of electrical impulses typically recorded on a magnetic tape. In digital systems the electrical impulses are further refined by a computer into a series of numbers that are recorded and that can be retrieved by other computers and displayed as images.

The American corporation Ampex first demonstrated a working video recorder in 1956. In the early 1960s video technology was used for instant replays in sports and the breaking events of President John F. Kennedy's 1963 assassination. Video cameras and systems were developed for surveillance and other uses. The Japanese manufacturers took the lead in developing consumer video recorders. Sony introduced the ½-inch Portapack in 1965 and the ¼-inch U-matic cassette system in 1969. These were adopted in the educational market and also in the adult film market. But it was in 1975 that the ½-inch cassette systems captured the global consumer market. At first there were two formats, Sony's Betamax and JVC's VHS, but within five years VHS dominated. The digital versatile disc (DVD) became the dominant video format after its introduction in 1997.

The video revolution was sparked by a pent-up desire of people throughout the world to change their use of television. Television critics were scornful of television’s “vast wasteland” of poor choices in the United States and no choice in other countries. However, enhanced choice was a secondary reason for most VHS purchasers. The most important motivation was to watch shows at the time and place that was convenient for the viewers (time shifting). Thus video technology became part of the sociological phenomenon of a time crunch. This function of video was not imposed by corporations but was the result of a “consumption junction” (a term coined by Ruth Cowan in “The Consumption Junction” [1987]) among users, manufacturers, and content providers.

There was some experimentation with original programming for video. But video's overwhelming use was to extend the global market for Hollywood films and television shows and the mainstream values they convey, fitting a general pattern of “suppressing [video’s] radical potential” (Winston 1998, p. 11). Raymond Williams’s concept of mobile privatization is an influential way to understand video use. He deduced that broadcasting was a culmination of a century-long pattern of privatizing popular culture. People use television to make their homes the center of their lives. Video dramatically accelerated this trend. The additions of downloading movie and television clips on the computer, the cell phone, and the I-pod have gone even further in the private viewing of filmed entertainment.

Diaspora communities use video technologies for ready access to their home cultures. However, this direct access has weakened specialized movie theaters and has lessened the opportunities for theater bookers to introduce the audience to unknown titles.

The art of filmmaking has changed. The mainstream American film industry dramatically merged into transnational media conglomerates attracted by the new video revenue (Wasser 2001). Video became the most important market, surpassing the theatrical box office. Story lines and characters are sold across a variety of media, from games to merchandise.

Video games have influenced narrative film aesthetics toward visceral effects that seduce the audience into experiencing the repetitive thrills and spills of movement and sound at the expense of character development and plot logic. To make people feel the experience of the movie, filmmakers have increasingly turned toward another aspect of video technology, computer generated images (CGI). Video shifted experimental filmmaking from the art house to the art gallery. Adult filmmaking is entirely in video.

Video technology has enabled the large trends of mass culture. On the industrial end, industries have consolidated. The promise of grassroots video making has rarely caught the mass public’s attention. One interesting example is the explosion of cheap fictional videos in Nigeria. On the consumer end, audiences have fragmented as viewers use video to facilitate a flexible work and leisure balance focused on consuming culture in isolated domestic spaces.

TECHNOPHOBIA
The word technophobia derives from the Greek words techne, an art or craft, and phobia, fear. As Hal Hellman notes, this word is most often used to refer to fear: “fear of
technology, fear of science, fear of change in general” (Hellman 1976, p. xi). The customary use of the word has been pejorative. Thus Daniel Dinello remarks that technophobia has been “deployed mainly by rabid technophiles who believe that questioning technology’s direction is crazy if not satanic” (Dinello 2005, p. 8). However, the word has come to refer not only to fear of technology or dislike of particular technologies but to general critiques of technology.

Champions of technology like Hellman allege that critics of technology are motivated by fear and anxiety, a charge implying that technology critics suffer from a psychological condition. In his 1998 publication the psychologist Mark J. Brosnan elevated this ad hominem approach to academic respectability by developing a model of the cognitive and psychosocial factors that might account for feelings of fear and anxiety about technology.

Like the word technocrat, technophobia can be used ironically. Dinello, for example, appropriates the label technophobe for the critic of technology. Rather than pursue questions of definition further, however, a brief and selective discussion of critiques of technology follows.

Technology critics represent various ethical and social perspectives. Some, such as Jacques Ellul and Martin Heidegger, see technology as dehumanizing or as an expression of inauthenticity or idolatry. Others, such as Langdon Winner, critique technology because of its political or social effects, for example, its threat to political values such as freedom and democracy. Still others, such as Carolyn Merchant and Nancy Lublin, examine technology largely on account of its gendered qualities or its damaging environmental effects.

All these lines of critique share the view that there exists a unified ensemble called “technology” as such, a phenomenon that is in some sense “autonomous” (Winner 1977), operating through a logic of its own in which human decisions do not count. This view challenges technological optimism on the part of liberals and Marxist socialists (e.g., Karl Marx’s optimism that what matters is not technology as such but which class controls technology). “Technophobes” do not merely allege that technologies are evil because oppressors control them and would be beneficial under a different form of social organization. Rather, they claim that an irresistible logic of technological autonomy trumps all forms of social organization and political agency, both individual and collective. The technology critic Winner, for example, refers to “reverse adaptation” (Winner 1977, pp. 226–251), a perverse logic in which political and other social ends have become determined by the means necessary to achieve them. For Winner, this and other characteristics of autonomous technology render democratic self-governance virtually impossible. As Henry Jenkins (1999) notes, technology as such may be said to constitute, not merely reinforce, systems of power and social control, leading to violations of human freedom and civil liberties. Ironically, the claim that technology erodes freedom may be encouraged by technophile arguments that technological development is historically irresistible and hence uncontrollable by political or other means.

The term Luddite is commonly used to characterize technophobes. Yet the early-nineteenth-century Luddites did not fear all technology. Rather, they attacked the specific technologies of textile production that they saw as oppressive. Over two centuries, however, technology critiques shifted from a focus on production technology to an emphasis on the technologies of consumption, entertainment, education, and so forth. In the early twenty-first century the technologies especially arousing “technophobic” hostility include biotechnology (genetic manipulation, cloning, and eugenics), nanotechnology and robots, nuclear energy, and of course computers and cyber technology, all of which provoke distrust because of their places in the sphere of consumption.

Whereas in the nineteenth century the Romantic movement was responsible for much technology critique, in the twentieth century technophobia became associated with the political left (Heidegger and Ellul are prominent exceptions), especially those portions of the cultural left not identifying with orthodox Marxism. Social critics, such as Max Horkheimer and Theodor Adorno, and radical environmentalists, such as ecologists and ecofeminists, for example, Merchant, have frequently expressed deep suspicion about technology and its “conquest of nature.” Conservatives, such as Thomas R. DeGrigori, especially in the United States with its market-libertarian traditions, tend to embrace technology or at least oppose government regulation of technology. Digital technology in particular flourishes in unregulated markets. On the other hand, certain technologies, such as biomedical technologies, are regarded by many conservatives as incompatible with religious faith. Of course the Old Order Amish are known for their avoidance of technologies associated with electricity and internal combustion on grounds of religion and community life.

The technological revolution shows no signs of abating. Hence technophobia in both senses—the psychological fear of technology and social critiques of technology—can be expected to flourish as well.

TECHNOTOPIA

A technotopia is a governance model in which policy decisions would be made by a technocracy, a depoliticized branch of government that is staffed by highly educated scientific and technical specialists, to the exclusion of politicians or interest groups. Admission is based purely on scientific and technical expertise, as demonstrated in open, competitive examinations. Free from political interference, the technocracy makes decisions based solely on scientific evidence and instrumental rationality. At the core of technopian thought is the conviction that technocrats will make better decisions than politicians. In their view, scientific and technological advances are inevitable and potentially beneficial, but only if they are managed by experts who can make scientifically driven decisions, free from political interference. In technopian thought, scientific and technological advances broaden the relevance of scientifically driven decision making until the technocracy wholly supplants conventional political systems. The wealth and abundance created by a correctly managed technological infrastructure, it is argued, would eliminate the inequities that made conventional politics necessary.

The various components of technopian thought are by no means new. For 1,300 years (605–1905), admission to the civil bureaucracy in dynastic China was based on a rigorous examination system. In New Atlantis (1627), the English philosopher and author Francis Bacon (1561–1626) envisioned a utopian society dedicated to fostering science and celebrating the achievements of explorers and inventors. In the eighteenth century, the French sociologist Henri de Saint-Simon (1760–1825) developed a recognizably technocratic governance model, in which an elite class of scientists and engineers would replace existing political institutions and make decisions on rational principles; Saint-Simon’s student, Auguste Compte (1798–1857), added a sense of historical inevitability to Saint-Simon’s formulation: Because the utility of the scientific method is matchless, it will ultimately be extended to all aspects of governance. In 1888, with the publication of Edward Bellamy’s Utopian novel Looking Backward, technocratic thought reached mass audiences in the United States and Europe; in the United States Looking Backward sold more than 1 million copies by the end of the nineteenth century. The novel describes a future utopian society in which a technocratically controlled industrial sector has been redesigned to serve human needs, resulting in abundance, leisure, learning, and social peace. In the early twentieth century (1919–1933), the Technical Alliance of North America, a group of New York–based scientists, architects, and engineers, called for the restructuring of the entire U.S. economy on scientific principles and the replacement of conventional politics by technocratic rule.

Although there has never been a society in which technocrats have wholly supplanted politicians, technocratic principles inform the civil administration of science and technology in most of the world’s advanced industrial economies, if to varying degrees. Closest to the technopian ideal, arguably, is the modern civil administration of France, founded in 1945 in the wake of the Nazi occupation. Entry into the highest levels of the administration requires a diploma from the École Nationale d’Administration (ENA); its graduates are called énarques, and they take positions in one of the two “grand corps of the state,” the administrative corps. Graduates of the leading French engineering school, the École Polytechnique, qualify for the better positions in the second of the two

Harlan Wilson
grand corps, the engineering corps. Both are designed to insulate the civil administration from political interference. Entry into either of the two diploma-granting institutions is based solely on competitive examinations. A host of administrative regulations and civil statutes prevent a too-cozy relationship between civil servants and business interests, especially the practice of pantoufle, in which bureaucrats who rule in industry’s favor are rewarded with lucrative private-sector positions. However, there are no such rules against civil servants going into politics; indeed, Jacques Chirac and Valéry Giscard d’Estaing, who have both served as presidents of France, are graduates of ENA.

The intent of France’s regulatory structure is clear: it is far better to have science and engineering affect politics than to have politics affect science and engineering. Although French citizens occasionally chafe at the perceived arrogance of their technocratic elite, it is also true that, in general, they trust the elite to make the right decisions concerning technology, and they take pride in France’s impressive record of postwar technological advances. For this reason, French government decisions to commit to nuclear power and to build high-speed rail lines throughout the country have met with little public opposition; in consequence, France is now a net exporter of electricity and is regarded as the world leader in railway technology.

Criticisms of technotopia focus on the risks of taking the public (and their elected representatives) out of the state’s decision-making apparatus. As part of their effort to stake out an autonomous zone of technocratic decision making, technocrats are tempted to elaborate and mystify their expertise in ways that make it appear to be far beyond the reach of the less educated; in so doing, they may be trying to cover up their inadequacies. At the same time, some technocrats express contempt for ordinary citizens who try to involve themselves in policy decision processes, believing that people with less-than-stellar educations could not possibly grasp the underlying science. Yet the public may question whether technocrats possess sufficient breadth of vision to make wise policy choices. Ultimately, technocrats must make policy decisions by trying to strike a balance between incommensurable factors, such as safety versus cost; critics of technocracy argue that these decisions need to be made transparently so that the public can evaluate them. Because technocrats are mainly drawn from the middle and upper classes, they may be suspected, as well, of class, gender, and racial biases. In the United States, for example, it has been argued that new hazardous waste disposal sites are disproportionately located within African American and Hispanic communities.

More fundamental criticisms question whether science and engineering are capable of providing an approp-
The modern telecommunications system uses a centralized network that relies on transmission facilities to send information between different locations. The origin of this network system developed from postal courier services established as early as the sixth century BCE in China (Xiong-jian and You-nong 1994). Postal service at that time was used primarily by the state to transmit commands and deliver orders to citizens and members of the armed forces. Providing an efficient long-distance communications system was key to governing a large geographic region and promoting economic growth. In succeeding years governments commonly sanctioned a single provider of courier service. Limiting communications services to one provider advanced efficient long-distance delivery of information by reducing costly duplication of services. Origins of a government-sanctioned monopoly can be traced back to Hapsburg’s Emperor Maximilian I in 1505. Establishment of the state-owned monopoly soon followed in 1614, as Prussia established a state-run courier service that handled letters and parcels for the entire empire (Stephan 1859). Prussia’s postal model served as the prototypical organizational structure for modern communications systems.

Over time, new technology such as the telegraph and telephone were generally integrated into the communications monopolies to form state-run post, telegraph, and telephone (PTT) companies in many countries. The development of the organizational structure of communications services in the United States is a notable exception to this form of integration. By the early nineteenth century privately owned telegraphic services in the United States were provided by Western Union, and postal service remained state-owned. Compared to postal delivery, telegraphy was a much faster way to transmit information because telegraphy used cables to transfer signals between locations. The invention of the telephone in 1876 by Alexander Graham Bell enhanced long-distance communications even further because it provided users the ability to transmit voice information over cable.

TELECOMMUNICATIONS GROWTH IN THE TWENTIETH CENTURY
Following the 1876 patent award for the telephone, Alexander Graham Bell, with support from a group of Boston financiers, established the Bell Telephone company. During its first years of operation Bell Telephone provided local communications services, and Western Union became the sole provider for telegraph communications. Over the next fifteen years Bell strengthened its monopoly status by extending its patent protection and developing a long-distance network to interconnect its operating companies. These operating companies formed the American Telegraph and Telephone Company (AT&T). The Bell system also integrated vertically into equipment production by acquiring Western Electric from Western Union. At the turn of the century Bell was continuing a pattern of acquiring independent companies and also had merged horizontally into telegraphy through partial acquisition of Western Union. These acquisitions contributed to the upsurge in the number of telephones in the Bell system, from 2,231,367 in 1905 to more than 15,000,000 by 1920.

Parallel industry growth occurred in other industrialized countries in western Europe and in Japan. By the late 1950s these countries had developed extensive wireline network systems that provided most of their citizens and businesses access to affordable telecommunications services. Protected from significant international and domestic competition, telecommunications monopolies became major employers offering high-wage jobs to telephone linemen, cable splicers, station installers, switchboard operators, and construction workers. The provision of well-paying jobs contributed to the expansion of these nations’ dynamic economies. Providing businesses the ability to communicate instantaneously over long distances created a competitive advantage domestically and internationally that further supported economic growth in industrialized countries.

Although maintaining an affordable and universal telecommunications system benefited society, government regulation of rates and subsidization of services introduced inefficiencies that grew as services expanded. The intent of rate regulation was to suppress price increases. In the United States this was achieved by setting maximum limits on telecommunications carriers' returns on investment. This type of a regulation, however, lowers the incentive to contain costs by encouraging overinvestment in capital and equipment in an attempt to generate greater profits (Averch and Johnson 1962). Government-approved subsidization of less lucrative sectors of the telecommunications monopoly was intended to allow carriers to finance expensive services with revenue from more profitable ones. In the United States relatively high prices in the long-distance sector helped support low prices for local services. Revenue from telecommunications services often supported more costly postal operations in countries with PTT-integrated systems (Noam 1992).

TECHNOLOGICAL ADVANCEMENTS AND TELECOMMUNICATIONS POLICY REFORM
New low-cost microwave technology changed the telecommunications industry because it became an economically attractive alternative to traditional long-distance services. The introduction of this technology in the late 1950s enhanced the competitiveness of long-distance
carriers by nearly removing the additional cost of transmitting information over additional distances (Waverman 1975). In the United States the 1982 AT&T consent decree required Bell operating companies to provide all long-distance carriers the same access to local customers that AT&T enjoyed. The decree also required the 1984 divestiture of the Bell operating companies from AT&T, and provided these companies the option of purchasing telecommunications equipment from suppliers other than AT&T’s manufacturing business.

Divestiture had the desired effect of promoting competition in the long-distance market. At the time of the breakup in 1984, AT&T had 96 percent of the business; by 1994 that share had fallen to 61 percent (Hendricks 1998). Long-distance users benefited tremendously from competitive prices offered by AT&T’s rivals. Ten years after divestiture, interstate long-distance prices had fallen 22 percent. This competitive pricing environment also promoted significant growth in this sector, as the overall value of long-distance service rose from $34 billion in 1984 to $64 billion in 1994.

Twelve years after divestiture, the 1996 Telecommunications Act continued the shift toward less government intervention in telecommunications by providing additional support for competitive pricing of local services. Encouraged by the increasing array of potential competitors for local telephone service—made possible by technical advances in switching technology, cable, and cellular services—this act allowed long-distance and cable providers access to local markets (Crandall and Waverman 1995). This act also made it easier for local carriers to enter the long-distance market.

REGIONAL TELECOMMUNICATIONS MARKETS

Technological advancements that contributed to the changing telecommunications market in the United States also helped bring about changes in telecommunications services in the rest of the world. Many regions have privatized their PTT monopoly in an attempt to promote greater production efficiency. The pace of change toward privatization varies considerably across regions, though, and is influenced in large part by the quality of their network infrastructures.

Europe By the latter part of the twentieth century, greater demand for specialized telecommunications services made the maintenance of a large integrated system increasingly impractical, especially for European carriers operating extensive wireline systems. Encumbered by the use of older equipment, telecommunications companies faced high costs associated with extending the network system to provide universal service to businesses and residential customers. In addition, heavy reliance on in-house equipment manufacturing limited access to alternative cost reducing technology (Noam 1992, pp. 81–82). Pressure from the United States and the European Union to open markets, and the opportunity to provide low-cost competitive services encouraged privatization of services.

A shift toward market-oriented policy in Europe originated in the United Kingdom with the 1981 British Telecommunications Act. This act separated telecommunications services from the postal service, privatized the public telecommunications network system, and liberalized the equipment sector. Funding accrued from selling shares of British Telecommunications, the newly privatized company, helped to finance acquisition of new equipment. Liberalization of the equipment sector gave British Telecommunications the opportunity to take advantage of competitive bidding from equipment suppliers. In this more competitive telecommunications industry British businesses benefited from lower rates and lower waiting time for phone installation (Noam 1992, pp. 129–131).

Asia Although changes in telecommunications policy and the industry’s growing significance as an engine for economic growth is nearly global, since the 1980s the transformations have been most marked in Asia. Societal support for change in this region is tied to overall support for growth in electronics and technology, especially in the Pacific Rim (Noam et al. 1994, pp. v–vi). The geography of this region—where countries along the Pacific Rim are physically separated by vast amounts of water, and immense countries such as China and India have inhabitants that live great distances from each other—underscores the importance of constructing a reliable system for transmitting information over long distances (Noam et al. 1994, p. 13).

Policies aimed at developing reliable, low-cost telecommunications operations varied greatly during the last quarter of the twentieth century. For instance, Japan was the Asian front-runner in privatizing its domestic and international services in 1984. Greater competition led to declining rates, to more efficient self-selection of carriers, and to easier interconnection of networks (Ito and Iwata 1994, pp. 449–451). In contrast, the Chinese government limited foreign participation in the operations of telecommunications networks by investing heavily in this industry through the extension of loans and preferential tax policies in the mid 1980s. Carriers in the telecommunications industry were exempt from repaying 90 percent of government loans, and could retain 90 percent of their profits, which translates to a tax rate of 10 percent compared to a rate of 55 percent for nonpreferred industries (Wauchkuhn 2001). Under this policy, telecommunications in China grew at an annual rate of 24.6 percent by 1999.
Latin America The lack of an extensive network system presented a major challenge to the growth of Latin American economies, and the need for funding to finance the upgrading of systems created openness toward privatization. This openness was also influenced by trade liberalization policies such as the North American Free Trade Agreement (NAFTA).

Early privatization during the 1980s saw heavy investment in wireline systems by foreign owners, but the more significant growth in telecommunications services occurred with a second wave of international operators investing in wireless technologies (Hughes 2002). Research on postprivatization telecommunications in Latin America shows appreciable modernization of network systems and marked reductions of phone rates for differing market structures. For instance, following privatization, the Mexican government supported a single dominant provider of telecommunications services, whereas Brazil divested its former state-owned monopoly into separate competing companies (Hughes 2002). Both of these countries enjoyed declining prices for telecommunications services. These findings reveal that a large number of competitors is not always necessary to achieve low phone rates; rather, the low-cost operations associated with modernization contribute to higher profits from increasing customer demand at low prices. This prospect of greater profits creates an incentive for price reductions, even in industries dominated by a single firm. However, for the longer term, price pressures from competitors may be needed to help ensure the continuance of low prices (Hughes 2002).

Africa Countries in Africa, especially those in sub-Saharan Africa, face a daunting task in developing their telecommunications industry. By the late 1990s African nations accounted for only 2 percent of the world’s telecommunications, even though these nations comprised 12 percent of the world’s population (Noam 1999, p. 3). The absence of an extensive telecommunications network can be traced to the lack of infrastructure investment by colonialists during the early and mid-twentieth century. Following decolonization in the 1960s, African governments were left with outdated telecommunications equipment and a severely undertrained workforce. In response to the need for improved intra-African telecommunications services, African nations agreed to the development of the Pan-African Telecommunications Network (Panaftel) in 1962. This project resulted in significant expansion of the continent’s network. Gains from this project slowed dramatically by the late 1980s as problems arose with standardizing switching systems, and incompatibility among carrier techniques hampered further development (Nuruddin 1999, pp. 258–259). These difficulties ultimately led to the discontinuation of international funding for the Panaftel project.

International support for modernizing the telecommunications system in Africa did not stop with the decline of the Panaftel project, though: international development organizations such as the World Bank have pushed cooperation and privatization schemes for public telecommunications operations (Kone 1999, p. 161). Advanced wireless technology that avoids the need for heavy investment in wireline equipment offers the promise of speedy progress toward modernization for developing nations in Africa and elsewhere.

SOCIETAL BENEFITS
Modernization of telecommunication services provides important societal benefits other than simple economic growth; for example, modern systems make it easier to quickly obtain vital information needed to provide quality healthcare, and they provide quick access to critical information needed to lower safety and security risks. In addition, new technologies provide workers with well-paying jobs (Peoples 1998). These employment gains do come at a cost, though, as labor-saving technology such as digital-switching systems have significantly reduced demand for switchboard operators. Jobs as union telecommunications workers are also less prevalent in this industry as liberalization policies facilitated an influx of nonunion carriers in the United States. Nonetheless, policies promoting competition have contributed to increased industry employment.

Despite the impressive societal gains associated with modernization and competition in telecommunications, challenges still remain. The disparity in the quality and availability of telecommunications services between developed and developing countries remains high, even though mobile service has made access to the telecommunications network easier for citizens in developing countries. There is room for greater societal gains even in developed countries. For instance, phone rates for local service increased following liberalization policies in the United States in large part because the high cost of connecting to access lines presents a significant entry barrier into local telecommunications markets. Still, if the recent history of this industry is a reasonable guide, it is highly probable that technological advances will contribute to overcoming these lingering challenges.

TELEOLOGY

The term *teleology* (from the Greek *telos*, meaning *end*) refers broadly to end-directedness, the idea that some things exist, have certain traits, or do certain things for the sake of some end. Many familiar cases of teleology are directly psychological, as when someone goes to the store in order to get milk. Here the behavior is intentional and the end is the object of the agent's intention. In other cases, involving artifacts, psychology plays an indirect but equally crucial role through design and use. For example, a spark plug exists, is present in the engine, and sparks at a certain point in the combustion cycle for the sake of igniting the fuel. Though such objects have no intentions of their own, they have proper functions—things they may be said to do for the sake of some end, as opposed to other things they just happen to do (such as the spark plug's making a noise when it sparks).

The most interesting questions about teleology concern living things. We commonly apply teleological concepts to the parts and features of organisms. The heart, for example, is said to have the proper function of pumping the blood, which in turn occurs for the sake of blood circulation and the biological ends of nutrient distribution and waste removal; pumping the blood is what the heart is for in the organism, as opposed to other things it does merely as side-effects (such as making a *lub-dub* noise). This is a teleological claim analogous to claims about artifacts, and it licenses similar function-based evaluations: Just as a spark plug that does not fire under the right conditions is a defective spark plug, so too a heart that fails to pump in certain ways under the right conditions is a defective heart. Similar points may be made even about the parts and features of plants—for example, a color pattern on a flower may have the biological function of attracting pollinating insects, this being what that adaptation is for in the life of such plants. The question is whether it is legitimate to apply teleological concepts to the natural world in this way and, if so, how this application is to be understood.

It might at first seem that all uses of teleological concepts in biology are ruled out by neo-Darwinian evolutionary theory. Certainly the theory does reject the idea that the process of evolution is teleological. It is another question, however, whether the products of evolution—the parts and features of evolved organisms—might stand in teleological relations. In fact, many philosophers of biology agree that natural selection itself provides a basis for teleological judgments about adaptations and their relevant effects. This is because natural selection mimics design in an important respect. A designer makes a spark plug the way it is and puts it in the engine so that it will spark and ignite the fuel, and this means that these effects partly explain (via the designer's intentions) the presence of the spark plug in the engine, setting them apart as proper functions and ends served by the spark plug. Natural selection does not, of course, deliberately do anything or act with any foresight, but it still yields a similar relation between an adaptation and certain effects it has. In the case of the evolved color pattern, for example, the effect of attracting pollinating insects partly explains (via

---

**James Peoples**

---

natural selection) the trait’s coming to be a standard feature of the evolved species, setting this effect apart as specially relevant to the formation and life of this species of plant. Many have argued that this provides a basis for sensible talk of proper functions and ends in connection with biological adaptations.

The above approach sharply contrasts with any approach that seeks to explain teleological facts about organisms by attributing teleology to the processes by which species are formed. A common form of creationism, for example, posits direct creation of each species by a divinity, giving organisms a design-based teleology analogous to that of artifacts. Intelligent design theory, by contrast, may accept evolution and common ancestry, but still posits supernatural direction of evolutionary processes on the grounds that neo-Darwinism alone “cannot possibly” explain the evolution of certain complex structures. Proponents of intelligent design argue, for example, that providence guides the genetic mutations upon which natural selection acts.

While the doctrine of special creation has been discredited by a wealth of empirical evidence for evolution, intelligent design theory is trickier. Because there is no way to demonstrate the absence of divine intervention in historical processes, the theory can never be disproved. For this very reason, however, it also falls plainly outside the scope of science. The biological work cited by proponents of intelligent design would remain within science if it were used simply to point out puzzles and shape scientific research projects to try to solve them. But by treating the puzzles as grounds for embracing supernatural hypotheses, intelligent design becomes a religious alternative to the scientific enterprise rather than a scientific alternative to neo-Darwinism, as its proponents often claim it to be when advocating its inclusion in public school curricula.

Historically, the track record for the God-of-the-gaps approach—that is, appeals to the supernatural to explain whatever is currently difficult to explain scientifically—has not been impressive, as claims about what science cannot possibly explain are steadily overturned. Still, despite its not being science, intelligent design theory could of course turn out to be true. If it did, it would provide for a partially design-based biological teleology and a purposive direction for evolution itself. Strictly speaking, theists could have this general result even without embracing intelligent design at the level of natural processes. They could, for example, posit divine influence in the shaping of the background laws, allowing for a more general divine purpose behind creation without the micromanagement of evolution. It is worth noting that at least for part of his career Darwin himself was not adverse to that idea, and similar claims have been advanced outside of biology as well. Some have argued, for example, that a divine intelligence is necessary to explain the highly unlikely confluence of “finely tuned” physical laws, physical constants, and cosmological conditions that was crucial for the eventual emergence and evolution of life in the universe. According to such a view, which is not logically inconsistent with neo-Darwinian evolutionary theory, there could be a very general design-based teleology in addition to the teleology rooted in natural selection.

TELEVISION

Television is one of the most significant communications inventions. Television has fundamentally changed the political process, our use of leisure, as well as social relations among family and friends.

Television was not developed by any single individual or even a group of people working together. Scientists and visionaries imagined a device that would capture images with sound and transmit them into homes since the 1880s. The word television was first used at the 1900 Exhibition in Paris. Scottish inventor John Logie Baird (1888–1946) was the first person to provide a television transmission in October 1925, and he subsequently demonstrated it to the British public on January 26, 1926. On December 25, 1926, Kenjiro Takayanagi (1899–1990) displayed the first image in Japan. The technology improved slowly with athletes participating in the 1936 Olympic games in Berlin able to see some poor quality images of the games. In 1936 France and
Germany began television programming. In Great Britain King George VI's coronation from Hyde Park Corner on May 12, 1937, was the first broadcast of its kind, and the first U.S. election reported on television was on November 8, 1941, where news of Franklin Delano Roosevelt's victory was transmitted to an estimated 7,500 sets.

The development of television was halted during the Second World War in Europe and North America where manufacturers directed their attentions to munitions. Regular television service reached ninety-six countries by 1973.

Many of the things we associate with modern television technology were patented or devised in television’s infancy. In 1928 Vladimir Zworyking (1889–1982) owned the first U.S. patent for an all-electronic color television; however, the development did not come to fruition for another twenty-five years. During the 1939 World’s Fair in New York, television could not only receive audio and video images, but it was also designed to record those images, foreshadowing video recording devices (VCRs). And Baird later patented a 600-line electronic high definition color system in Britain in 1945.

TELEVISION’S GOLDEN AGE

The golden age of television is associated with the years 1949 to 1960 when American television viewing consisted of a variety of entertainment programming. The burgeoning prosperity and optimism of post–World War II influenced the spread of television. As more people were able to purchase televisions the demand for content grew. Early television programs offered revamped radio programs. There was news and information programming, but those tended to be of short duration. A similar golden age is associated with British television. Early programs were reworked vaudeville acts and radio shows. Later situational comedies such as I Love Lucy and The Honeymooners would create new talent and genres.

The shared experience of watching key television programming provided an avenue for discussion and next-day water cooler conversation. As television matured so did the content, with programs such as All in the Family offering political and social commentary on issues ranging from race relations to the Vietnam War. Television’s depiction of the family changed through time as well. While initial programming presented unified traditional families with bread-winning fathers and stay-at-home mothers, later programs depicted the breakdown of the traditional family dealing in both fiction and nonfiction with divorce, remarriage, blended families, and later, with same-sex unions.

Not only did television provide scripted programming, but it also broadcasted major sporting events. The first televised hockey game between the Montreal Canadiens losing six-to-two to the New York Rangers in Madison Square Gardens was seen on February 25, 1940. Television is also closely associated with the increasing popularity of the Olympic games, soccer, American football, and baseball.

With technological improvements, viewing time increased as well as television’s influence on the public and politics. In 1947 there were only 60,000 American homes with television sets; by 1950 this figure grew to 12.5 million. Televisions are now found in nearly every home in the United States and Europe. In the developing world, the allure of television is so great that some want television before other communications devices such as telephones.

The hold of major networks on audiences soon dissipated with the advent of cable and specialty television programming. Rather than having a system where the networks catered to a common denominator of programming, the proliferation of specialty programs allowed people to view content that interested them specifically. Moving from analog to digital signals allowed for a so-called 500-channel universe where any specific interest could be satisfied, from golf to cooking; from sport to fashion; and from all news to pornography. As a result of these technological changes, the era of the mass audience was over. While there remain a few programs that can attain mass audiences, the market has been so fragmented that networks must compete for an ever-shrinking television audience.

EFFECTS ON CHILDREN

The rapid adoption of television fundamentally changed modern society. Television has been blamed for the decline in civil society, the breakdown of the family, suicide, mass murder, childhood obesity, and the trivializing of politics.

Children have been the target of broadcasters since the 1950s. Initially American broadcasters provided twenty-seven hours a week of children’s television programming. By the 1990s there was twenty-four hour a day programming available to children. Children in Canada spend fourteen hours per week (Statistics Canada) watching television, while American children spend twenty-one hours per week (Roberts et al. 2005, p. 34). Some surveys suggest that British children have the highest rate of television viewing in the world. There are several concerns associated with television and children’s viewing patterns. Many researchers have noted the link between the advent of television and increasing obesity and other weight-related illnesses. The time spent watching television is time not spent playing outdoors or in other physically challenging activities.

High television viewership of violence is linked to an increase in violent children. Prolonged exposure to violent
Television programming has shown that children can become more aggressive, become desensitized to violence, become accepting of violence as a means to solve problems, imitate violence viewed on television, and identify with either victims or victimizers.

Despite the negatives associated with television, it remains a powerful tool in shaping and educating children. While many point to the destructive nature of television, there are others who acknowledge television's positive impact. Researchers and programmers have developed content that has positively influenced children. Early studies on the PBS program Sesame Street found that children who viewed the program were better readers in grade one than students who had not watched the program. Programs were developed not only to help with literacy, but with other subjects as well as socialization, problem solving, and civic culture.

Notwithstanding the positive effects of children and television viewing, high television viewing has been associated with a decline in civic culture. As people have retreated to their homes to watch television, they have been less inclined to participate in politics either by voting or by joining political parties. In addition television viewing means that people are not interacting as much with friends or neighbors. What is more, television viewing also has been associated with an overall decline in group participation as well as volunteerism.

**ADVERTISING AND OWNERSHIP**

The issue of ownership of content and transmission was debated from television's onset. In 1927 the U.S. Radio Act declared public ownership of the airwaves. They argued that the airwaves should "serve the PICN—public interest, convenience, and necessity." Because of this understanding of the public owning the airwaves, it set the stage for regulatory bodies around the world licensing stations according to content regulations. Taking the issue of public interest one step further, the British government founded the British Broadcasting Corporation (BBC) in 1927. Other countries followed establishing their own public broadcasting systems. The United States lagged behind other nations by adopting a Public Broadcasting Service (PBS) in 1968. With the increasing adoption of television, many countries found the need to create new regulatory agencies. In the United States, the U.S. Federal Communications Commission (FCC) was created as an act of Congress on June 19, 1934.

The most successful television enterprises are closely associated with advertising. From the outset the way in which television content was funded was through the pursuit of advertising dollars. As a result it has often been said that television does not bring content to audiences, but instead it brings audiences to advertisers. The *propaganda* model of the media, coined by Edward Herman and Noam Chomsky in their 1988 publication *Manufacturing Consent: The Political Economy of the Mass Media*, argues that the media uphold the dominant ideology in America. The five pillars of the model focus on ownership, advertising, sourcing, flak, and anticommunism. This model has been linked to other western media systems, but is most fitting in the United States where the power of the media rests with the owners.

Television's hold on the public imagination stems in part because of its ease of transmission. No one needs any special skill to receive the messages. All that is required is a television that can pick up a signal. More important, television influences our view of the world precisely because images are transmitted into people's homes. Since its inception, television transmissions have had the power to change our perceptions of world events. Starting with the Vietnam War and continuing to a myriad of events from the arms race to Tiananmen Square, and from the Civil Rights movement to the war in Iraq, television has become synonymous with the phrase "the whole world is watching."

TEMPERAMENT

In contrast to theories that attribute variation in behavior primarily to socialization influences, temperament refers to early-appearing emotional, physiological, and attentional tendencies that, in interaction with the environment, organize the development of stable traits. Because a common focus on consistency of traits over time unites concepts of personality and temperament, temperament has been construed as an intrinsic core around which personality emerges.

A useful distinction between temperament and personality is that the latter includes a broader array of constructs involving more socially constructed cognitive attributes, such as morality, self-concepts, and beliefs. Temperament refers to more basic and overt behavioral tendencies. The more specific nature of temperament allows for coordination of adult research with investigations of infants and nonhuman animals, including the exploration of neural systems associated with temperament traits.

Although ideas regarding temperament appear in the writings of Greco-Roman physicians, the preeminence of the socialization models inherent in learning and psychoanalytic theories in the first half of the twentieth century prevented temperament concepts from receiving substantial attention from developmental psychologists until the 1960s. Two developments contributed to increased consideration of temperament during the latter half of the twentieth century. The first involved observations made by Alexander Thomas and Stella Chess (1977) of children experiencing psychological dysfunction despite being raised in well-functioning homes. A second and more recent advance concerns increasing sophistication of neuroscience measures and corresponding theories that have allowed for greater precision in linking activity in the brain to individual differences in behavior.

TEMPERAMENT DEFINED

Subtle differences exist in the boundaries researchers have used to define temperament. Early descriptions of temperament primarily considered susceptibility to, and severity and pervasiveness of, affective displays and included evidence of genetic origins and appearance during the first year as hallmarks (Goldsmith et al. 1987). More contemporary perspectives soften these boundaries, additionally focusing on attentional and behavioral processes that alter the course of emotional responses, and allowing for environmental influences.

In the early twenty-first century, the most frequently cited definition of temperament is that proposed in 1981 by Mary K. Rothbart and Douglas Derryberry: constitutively based, relatively stable individual differences in emotional, motor, and attentional reactivity and self-regulation. The term constitutively refers to the role of biological underpinnings, shaped by heredity, maturation, and interactions with the environment. Stable refers to consistency both over situations and over time. Reactivity involves latencies, intensity, and duration of behavioral, affective, and physiological reactions to changes in the environment. Self-regulation refers to attentional processes, such as orienting and focusing, and behaviors, such as approach and withdrawal, that modulate reactivity.

METHODOLOGY AND DIMENSIONS OF TEMPERAMENT

Temperament is assessed through structured and naturalistic observations made in the laboratory and the home, and through parent- and self-report questionnaires (the latter from older children and adults). Naturalistic observations maximize external validity but are time-consuming and often demonstrate low consistency across measurement periods. Laboratory assessments allow for tighter control of eliciting contexts, but ethical and practical limitations constrain the type of traits that can be assessed and may result in carryover effects from one procedure to another. The use of questionnaires allows for measurement of child behavior across a wide range of situations but can be contaminated by reporting bias. Despite the differences among assessment strategies, Rothbart and John E. Bates, in their 2006 examination of several studies, demonstrated convergence across measures.

Because of their ability to efficiently assess multiple aspects of behavior, questionnaires have been instrumental in identifying important temperament dimensions. Studies conducted in the late 1990s and early 2000s have used factor analysis of finely differentiated attributes to elucidate high-order traits. In a 2001 paper, Samuel P. Putnam, Lesa K. Ellis, and Rothbart describe three similar factors that have emerged from different questionnaires and across the lifespan. These factors also bridge gaps between personality and temperament traditions, as they bear resemblance to three of the “Big Five” traits commonly reported in adult personality studies. The first, labeled surgency and resembling the personality construct of extraversion, includes activity level, sociability, impulsivity, and enjoyment of high-intensity activities. The second, negative affectivity, is conceptually similar to neuroticism and includes sadness, anger, fear, and discomfort. The third, referred to as orienting/regulating in
infancy and as effortful control thereafter, includes enjoyment of low-intensity activities, attentional focusing and shifting, and inhibitory control, and bears similarity to the personality construct of conscientiousness.

TEMPERAMENT STABILITY AND DEVELOPMENT

Rothbart and Bates (2006) review studies of twins and adopted children that indicate significant genetic effects on temperament, as well as describe more recent molecular genetic investigations that suggest specific genes underlying temperamental traits. Evidence of biological underpinnings suggests that temperament traits should be stable across time, and this is true to an extent. Several studies have supported predicted associations between infancy and middle childhood, but these relations are often fairly modest. More robust stability is found after the age of three years, and longitudinal studies conducted by Avshalom Caspi and colleagues (2003) have confirmed relations between temperament at age three and personality at age twenty-six. In their 2000 review, Brent W. Roberts and Wendy F. DelVecchio found that stability estimates increase throughout much of adulthood.

Multiple factors account for increasing estimates of stability with age. The first concerns the difficulty of measuring the same construct at differing developmental points, as both the expressions and elicitors of temperament change with maturation. The second explanation is that real change in the traits may occur because of environmental influences, and plasticity in systems underlying temperament may decrease over time. Finally, it is now recognized that temperament itself develops. Of primary importance is the emergence of regulatory capabilities that modulate earlier-appearing reactive tendencies. One such shift occurs in the second half of the first year, as fear-related behavioral inhibition alters the expression of approach motivation.

Throughout the toddler and preschool periods, dramatic increases in effortful attentional and behavioral control allow for greater flexibility in the expression of other predispositions. Individual differences in maturation rates compound the appearance of instability.

The dominance of learning theories in explaining individual differences has given way to greater appreciation for inborn, biologically mediated predispositions that shape personal characteristics. Several temperament characteristics exhibit normative developmental change but also demonstrate interindividual stability over long periods. With advances in both measurement of genetic and neural processes and in theories explaining how biology and environment interact to form developmental pathways, our understanding of temperament is sure to show dramatic gains in the near future.

TERM LIMITS

A “term limit” is a rule that prevents government officials from serving for more than a specified number of terms. More than a technical electoral regulation, a term limit reflects the manner in which citizens envision their leaders: Should politicians be temporary servants of the public who rotate relatively quickly into and out of office, or a corps of experts who remain in power as long as they earn majority support? The main rationale behind mandating turnover through a term limit is that it will bring fresh perspectives to government and ensure responsiveness to voter demands, at the potential cost of losing knowledgeable veterans. Term limits have been debated, and intermittently enacted, throughout the history of democracy.

One ancient Athenian legislature, the Boule, placed a one-term limit on service, an idea argued for by Greek philosopher Aristotle in the fourth century BCE. There were term limits in the first U.S. Congress established under the Articles of Confederation, although the idea was later rejected at the Constitutional Convention because many of the Founding Fathers thought it made Congress weak. The constitutions of Mexico and Costa Rica impose short term limits on both their legislators and presidents. The president of the United States is limited to two terms in office, as are most state governors. The term limit laws that have provoked the fiercest debate and had the most profound effects in America have been the limits enacted since 1990 on state legislators.

In 1990, voters in California, Colorado, and Oklahoma passed citizen initiatives, which for the first time imposed term limits on their state representatives. Two years later, ten more states enacted limits, all of them through initiatives and many of them spurred by the efforts of the “U.S. Term Limits” organization. Predictably, this reform was much less popular among state legislators themselves. Louisiana’s state legislators were the only ones to impose limits on their own term lengths even though they did not face the threat of an initiative. By the end of the decade, twenty-one states had passed term limits. In four of them (Massachusetts, Oregon, Washington, and Wyoming), judges overturned these initiatives on technical grounds, and legislators repealed limits in Utah and Idaho. The term limits that remained in effect in fifteen states varied considerably in lengths and strictness. Michigan’s initiative prevented state legislators from serving more than six years in the state’s House and eight years in the Senate, banning them for life afterward. Louisiana’s law, crafted by legislators themselves, imposed a twelve-year limit in each house, and only mandated that legislators sit out a single term before they are eligible to run again. But regardless of these important provisions, all term limit laws proposed were based on a similar line of reasoning and have faced a common set of criticisms.

Proponents of term limits contended they would bring a return to the ideal of the “citizen legislator” who carries the concerns of average voters into office, then quickly leaves to rejoin their ranks. Mandating turnover would replace entrenched incumbents with representatives who were closer to the people. These new lawmakers would not be tainted by allegiances to interest groups or captured by the bureaucracy, the argument went. Because new lawmakers could not plan a long future representing one district, they would be freed from catering to the whims of a narrow constituency and would make decisions with the common welfare in mind. To the supporters, term limits would make it more likely that exiting legislators “would anticipate careers in the private sector and therefore would, as they legislate, think about what it is like to live under the laws they make” (Will 1992, p. 201).

Those who argued against the imposition of term limits in the states and upon members of Congress warned that these laws would throw out of office many legislators with decades of institutional knowledge. Losing this expertise would leave the legislative branch impotent against a massive and well-informed executive branch. Some opponents predicted that after jettisoning their most senior parliamentarians legislatures would see their lawmaking process grind to a halt. Lobbyists and unelected staff would fill the vacuum of information and power, leaving voters poorly represented. One opponent compared the career paths of termed-out legislators to that of Cincinnatus, a Roman farmer much admired by the founders of the United States, who has become the archetype of the citizen legislator, charging that limits “would put at risk the independence of legislators contemplating exit who, rather than returning Cincinnatus-like to their waiting plow, prefer some sort of future elsewhere. Even Cincinnatus might be tempted to send a farm subsidy or two homeward in advance of his return” (Polito 1993, p. 7).

Given that term limits have removed hundreds of legislators from office in many states, it is possible to judge the predictions made by both term limits’ boosters and adversaries against the empirical record, gleaned from election statistics, surveys of legislators and statehouse observers, and state legislative archives. Not surprisingly, term limits have had their intended effect of greatly increasing turnover. This has brought new faces and perspectives into office, and accelerated gains in representation for racial and ethnic minorities in the states with changing demographics. Yet getting rid of incumbents has not made state legislative elections more competitive; term limits did not cut into the average margin of victory in these contests or lead to more seats changing party hands.

When new legislators come to office after term limits, surveys show, they do tend to think more about
statewide concerns than about the demands of their districts. But they also spend less time keeping in touch with voters and working to solve constituent problems, compared to legislators who do not face limits. Although the legislative process has not devolved into chaos anywhere, committees tend to give bills less scrutiny after term limits and the laws that are ultimately produced are usually shorter and narrower. One of the clearest findings about term limits, confirmed in examinations of archival records as well as in interviews with a range of political observers, is that they dramatically reduce the power of the legislative branch. Governors exert more influence over crafting state budgets once limits are imposed, and legislators spend less time on oversight of the executive branch.

In many states as in the federal government, the chief executive also faces term limits. Since the ratification of the Twenty-second Amendment in 1951, U.S. presidents have been allowed to serve for only two elected terms in office. Thirty-four states imposed term limits on governors, with all but one state preventing governors from serving for more than two terms—Virginia’s one-term limit is the exception. Such limits have been motivated less by the desire to bring new perspectives into office and more by concerns about halting the accumulation of power over time into the hands of a single leader. The Twenty-second Amendment was proposed by a Republican Congress not long after Democrat Franklin Delano Roosevelt (1882–1945) had won his fourth term. The amendment was proposed in order to prevent similarly popular future presidents from holding the office for life. Enacted for similar reasons, term limits on governors have had less profound effects than limits on legislators because they rarely bring political newcomers into office and serve to solidify rather than disrupt the normal rate of turnover.

In American statehouses, by contrast, term limits do much to shape the legislative landscape. It appears term limits will be a permanent feature of state political life since the courts have affirmed term limits in principle (in the Bates v. Jones decision) and most attempts to repeal or relax limits have met with staunch public opposition. The spread of term limits across the nation has also apparently come to a stop because they have been passed in nearly every state with an initiative process and the courts have made it clear that states cannot impose term limits on their members of Congress (in U.S. Term Limits, Inc. v. Thornton). This leaves the nation in the midst of a large-scale experiment with a central rule of democracy. Approximately a third of state legislatures operate under the same sorts of limits that were imposed under the Articles of Confederation, while two-thirds follow the guidance of the Constitutional Convention to leave legislators unhindered. The coming decades will test the wisdom of each system.

**TERM STRUCTURE OF INTEREST RATES**

SEE *Interest Rates*.

**TERMS OF TRADE**

By terms of trade, economists generally mean commodity terms of trade (CTT), or net barter terms of trade (NBTT), given as a price or unit value ratio. For this ratio, it is appropriate to use the term *unit value* rather than *price* because different heterogeneous commodities are aggregated into a single commodity category such as exports or imports.

Commodity terms of trade of a country are defined as the unit value (price) of exports of the country divided by its unit value (price) of imports. Commodity terms of
trade between two regions, say, the North (industrially
developed) and the South (less developed), is defined as
the unit value (price) of exports of the North to the South
divided by the unit value (price) of exports of the South
to the North. The commodity terms of trade index
measures unit gains from the trade amount—imports (i.e.,
the volume of imports) that are available for one unit of
exports.

**INCOME TERMS OF TRADE**
The income terms of trade (ITT) is an index of the value
of exports divided by the unit value (price) of imports—
the value of exports measured in terms of import goods. It
corresponds to the commodity terms of trade multiplied
by the volume of exports. ITT measures the purchasing
power of exports—the amount of imports that can be
financed by the total exports.

The use of ITT is often recommended in order to
correct shifts in the commodity terms of trade for changes
in the volume of exports. A fall in the terms of trade may
desirable if it leads to a significant expansion in export
volumes so that the value of exports rises. As a result the
capacity to import rises. The income terms of trade index
is designed to measure the net effect of a change in the
commodity terms of trade on the capacity to import or on
the purchasing power of exports.

In the dynamic context of world economic growth,
the volume of exports of a country or region often shows
a trend growth exceeding the rate of decline (if any) of the
commodity terms of trade, leading to a rise in its ITT. The
ITT of a country or region can rise along with its trading
partner as both can experience absolute gains from trade.
To measure the relative gains from trade, Prabirjit Sarkar
(1986b) recommended the use of the ITT of one country
or region as a ratio of that of the other.

**FACTORIAL TERMS OF TRADE**
In the process of growth, technical progress takes place
and factor productivity improves. As a result, the cost of
production may decline and prices may fall. A decline in
the commodity terms of trade may be precisely attributa-
table to this technical progress and cost reduction. To net
out this effect of technical progress on commodity terms
of trade, the concept of factorial terms of trade is used. If
the effect of technical progress on export prices or export
unit values is taken into consideration, this leads to single
factorial terms of trade. If the effects of technical progress
on both export and import prices or unit values are taken
into account, this leads to double factorial terms of trade.

To construct single factorial terms of trade (SFTT) of
a country or region, its CTT is multiplied by some index
of factor productivity in its export sector. To construct
double factorial terms of trade (DFTT) of a country or
region, the SFTT is deflated by the index of factor pro-
ductivity in the export sector of its trading partner. So
DFTT is CTT multiplied by the ratio of the indexes of
factor productivity in the export sectors of the trading
partners.

Because the factorial terms of trade is used as an indi-
cator of changes in welfare, which means changes in real
income per head, labor productivity is often used in the
calculation of factorial terms of trade. The SFTT index
bears on a country’s absolute welfare, while the DFTT
index bears on relative welfare between trading countries as
pointed out by the British economist John Spraos (1983).

**THE PREBISCH-SINGER HYPOTHESIS**
There is much controversy regarding the long-term move-
ments of the terms of trade of the South vis-à-vis the
North. This dispute centers on the Prebisch-Singer (PS)
hypothesis, which is associated with the works of two
United Nations economists, Raúl Prebisch and Hans W.
Singer. The essence of the PS hypothesis is the long-term
decline in the DFTT of the South vis-à-vis the North. In
the absence of appropriate historical data since the last
quarter of the nineteenth century both Prebisch and Singer
used CTT of primary products vis-à-vis manufactures as
the proxy of the DFTT of the South vis-à-vis the North for
two reasons. First, the South constituted mainly primary-
product exporting countries in contrast to the manufacture
exporting countries constituting the North. Second, pre-
suming that the technical progress and labor productivity
improvements took place at a higher rate in the North than
in the South, a decline in the CTT of the South would
imply a further decline in the DFTT of the South.

The Prebisch-Singer hypothesis was virtually dis-
card in mainstream economics in the face of strong sta-
tistical objections against it. Since the 1980s, a series of
studies undertaken by Spraos (1980), David Sapsford
(1985), Sarkar (1986a, 1986b), Sarkar and Singer (1991),
Grilli and Yang (1988), and many others questioned the
validity of the criticism and provided strong statistical
support for the Prebisch-Singer hypothesis, thereby bring-
ing it back into the limelight.

The core of the PS hypothesis has a divergence im-
plcation: In the process of long-term decline in the terms
of trade of the South, the standard of living of the poor
South cannot be expected to catch up with that of the rich
North. Both Prebisch and Singer argued that the fruits of
technical progress taking place in the northern export sec-
tor were distributed among the northern people through
higher wages and profits, leading to rising standards of liv-
ing because of strong labor unions and high monopoly
power of the capitalists. But the fruits of technical
progress in the southern export sector were transmitted to the North through lower export prices because of surplus labor, leading to weak labor unions and the lack of monopoly power of the southern capitalists vis-à-vis their northern counterparts. Thus the process of evolution and growth of the world economy through technical progress led to uneven development (as observed by Sarkar in 2000) and a long-term decline in the DFTT of the South.

TERROR

Although all living things must die, humans are the only species who are aware of this unfortunate fact. How does this knowledge affect us? Inspired by Ernest Becker's influential book, *The Denial of Death* (1973), social psychologists Sheldon Solomon, Jeff Greenberg, and Tom Pyszczynski developed terror management theory to explore the role that awareness of the inevitability of death plays in diverse aspects of human behavior. As of 2006, more than three hundred studies conducted in at least fourteen countries have supported the central ideas of this theory and have shown that awareness of death influences a broad range of behaviors that, on the surface, bear no obvious relation to the problem of human mortality.

Terror management theory suggests that the awareness of death in an animal that wants to live creates the potential for paralyzing terror. Humankind “solved” the problem of death by using its sophisticated intellectual abilities to give life meaning, value, and permanence, and by so doing, provided a means of managing the potential for terror that awareness of death creates. People manage terror by immersing themselves in a cultural worldview that provides a theory of reality, standards for valued behavior that confer self-esteem, and the promise of literal or symbolic immortality to those who live up to these standards. Literal immortality is provided by the religious aspects of the worldview that promise some form of afterlife; symbolic immortality is attained by contributing to and being part of something that continues long after one’s individual death, such as families, nations, or other valued groups. To effectively protect against existential terror, cultural worldviews and self-esteem requires ongoing validation by others. Those who share one’s worldview and believe in one’s value increase faith in the worldview and self-esteem, whereas those who disagree with one’s worldview or one’s value undermine this faith. To maintain the anxiety-buffering effectiveness of these structures, people exert great effort to keep their self-esteem and faith in their worldview strong and to ward off any threats to these beliefs that might arise.

Consistent with the theory, research has shown that: (1) bolstering self-esteem or faith in one’s worldview makes people less prone to anxiety; (2) reminders of death increase one’s striving for self-esteem and meaning, one’s structuring of information about oneself and the world, and one’s favorable reactions to people and ideas that support one’s worldview and unfavorable reactions to people and ideas that threaten it; (3) threats to one’s self-esteem or worldview bring thoughts of death closer to consciousness; and (4) increasing self-esteem, faith in one’s worldview, or belief in an afterlife reduce the effects of reminders of death on defensive behavior. The effect of death awareness on human behavior is largely unconscious. People use self-esteem and their worldviews to defend against death-related anxiety when thoughts of death are on the fringes of consciousness; conscious thoughts of death are defended in ways more directly
related to the problem of death, by denying one’s vulnerability to disease or accident and promising to pursue a healthy lifestyle. When death-related thoughts come close to conscious awareness, this signals a potential increase in anxiety, which leads people to cling especially strongly to their worldviews and self-esteem and defend these structures against threat. These defensive reactions occur so rapidly that conscious fear of death is typically averted.

This work suggests that the problem of death lies at the root of the human quest for meaning and self-esteem, and that much human behavior is driven by the protection from existential anxiety that meaning and self-esteem provide. It also suggests that prejudice, hatred, and violence are often rooted in the threat to one’s protective shield posed by those with worldviews different from one’s own. Support for this view comes from studies showing that reminders of death increase stereotyping, hostility, and aggression toward those with different worldviews, favoritism toward one’s group, and prejudice toward those from different cultures, nations, and religions. These processes have been shown to play an important role in international conflict and terrorism. Studies have shown, for example, that reminders of death have led young Iranians, who normally oppose terrorist violence, to increase their support for such tactics, and reminders of death have led young Americans, who normally oppose extreme military action, to support preemptive war and the use of weapons that would kill thousands of innocent civilians as part of the struggle against terrorism. This research shows that fear plays an important role in promoting support for violent solutions to the ongoing conflict in the Middle East.

This research also suggests that individual psychological problems are often rooted in breakdowns in the protection from core human anxiety that results when one’s self-esteem or worldview is undermined. Reminders of death increase the severity of psychological symptoms, such as spider phobias and obsessive hand-washing, among those prone to these problems. People tend to be most happy and well-adjusted when they are able to view themselves as valuable contributors to a meaningful world. Although people have little conscious awareness of its impact, the problem of death exerts an important influence on most of what they do.

**TERROR MANAGEMENT THEORY**

Terror management theory (TMT; Solomon, Greenberg, and Pyszczynski 1991) was derived from the work of the cultural anthropologist Ernest Becker (1924–1974), who in such books as *The Birth and Death of Meaning* (1962), *The Denial of Death* (1973), and *Escape from Evil* (1975) argued that the uniquely human awareness of death underlies a substantial proportion of human behavior. TMT posits that although human beings share with all life-forms a biological propensity toward survival, humans are unique in their awareness of the inevitability of death, that death can occur at any time, and that we are corporeal creatures no more important or enduring than barnacles, beets, and beavers. To assuage the potentially paralyzing terror engendered by this knowledge, humans embed themselves in cultural worldviews: humanly constructed beliefs shared by individuals in groups that provide a sense of meaning and significance and promises of symbolic and literal immortality to those who adhere to the standards of value prescribed by their culture.

While cultures vary considerably, they share the same defensive psychological function: to provide meaning and value and in so doing bestow psychological equanimity in the face of death. All cultural worldviews can ultimately be viewed as shared fictions, in the sense that none of them are likely to be literally true, and their existence is generally sustained by social consensus. Individuals surrounded by people believing the same things as themselves can be quite confident of the veracity of their beliefs. However, when one encounters people with different beliefs, this is posited to pose a challenge to one’s death-denying belief systems; TMT proposes that this challenge is a primary reason that people are generally quite uncomfortable around, and hostile toward, those who are different. Additionally, because no symbolic cultural construction can actually overcome the physical reality of death, residual anxiety might well be unconsciously projected onto other groups of individuals as scapegoats, who
are designated all-encompassing repositories of evil. Thus, responses to people with different beliefs might be to scapegoat them or berate them, or try to convert them to one’s own system of beliefs. In some instances, these dynamics might well lead to terrorism, war, and killing.

Empirical support for TMT (see Solomon, Greenberg, and Pyszczynski [2004] for a recent review) has been obtained in over two hundred experiments, primarily by demonstrating that reminders of death (mortality salience) instigate cultural worldview defense. For example, after a mortality salience induction, Christian participants reminded of death liked fellow Christians more and Jewish people less, Germans sat further away from a Turkish person and closer to a fellow German, and people were more physically aggressive toward someone with different political beliefs. Research conducted after September 11, 2001, demonstrated that reminders of death or the events of 9/11 increased Americans’ support for President George W. Bush and his policies in Iraq and conservative Americans’ support for the use of nuclear and chemical weapons in preemptive military strikes. Additionally, Iranians reminded of death were more supportive of suicide bombers and more willing to engage in martyrdom actions.

Most recently, TMT theorists have been devising ways to minimize or eliminate the adverse effects of death denial while exploring how confrontations with mortality can elicit what is most noble in the human animal.

TERRORISM
The study of terrorism is complicated by the fact that terrorism is a political rather than an analytical concept. The concept is closely related to major power conflicts, such as the cold war, nationalist conflicts, and—most recently—religious-political polarization; and its political use and academic definitions have changed accordingly. As a result, scholars of terrorism have not only looked at terrorism as a particular kind of political violence, such as assassinations, hijackings, or—most recently—suicide bombings, but have also been sensitive to the discursive use and impact of the term terrorism. What both lines of study have in common, however, is the notion that terrorism—both as a practice and a discourse—is meant to terrify. Both the perpetrators of terrorist violence and those who have the power to name a particular kind of violence as terrorism do so to create fear. The study of terrorism has therefore not only focused on those branded as terrorists but also on those who do the naming, such as the media, policymakers, and academics, as well as on how the term terrorism is itself a highly contested label.

Precisely because terrorism is a political term, there is little consensus on how to define the phenomenon. According to an often-used definition, terrorism resembles guerilla warfare to some extent while being distinctively different from it in others. Both are unconventional forms of warfare in which the state is attacked by groups of combatants lacking a fully armed military apparatus in order to bring about political change. However, whereas guerilla fighters primarily target military objects, terrorists also attack “soft” civilian targets in order to paralyze society. According to this definition, the Oklahoma City bombing by Timothy McVeigh in 1995 is terrorist, whereas the suicide attack by Shi’a combatants on American and French U.N. troops in Beirut, Lebanon, in 1983, killing 241 marines, is an act of guerilla warfare. Similarly, the Viet Cong fighting the U.S. army in Vietnam or the Algerian Front de Libération Nationale fighting the French colonial army in the 1950s were guerilla fighters, whereas the Irish IRA, the Basque ETA, or the West German Red Army Faction also attacked civilians and are therefore defined as terrorist.

Scholars who have focused on the perpetrators of “terrorist” violence have used various perspectives. Richard Rubenstein (1987), among others, analyzes terrorism as a political strategy with a particular genealogy rooted in the French Revolution’s régime de la terreur and nineteenth-century anarchism. Maximilien Robespierre and Louis Antoine Saint-Just as well as Sergej Nechaev and Michael Bakunin thus appear as the ideologues of terrorism. The thinking of the latter as to how to fight the all-powerful modern state, including the notion of the revolutionary vanguard, the provocation of the state, and the revolutionary moment, has subsequently influenced nationalist militants and left-wing revolutionaries of the twentieth century.

Another line of study has considered terrorism in relation to utopian belief systems and political eschatology. Rather than a strategy, terrorism is seen as a testi-
Terrorism

mony, an act of faith, and the outcome of radical collective fantasies about ideological, ethnic, or religious purity. These studies focus on processes of radical “othering” and satanization, the political use of traditions of martyrdom and sacrifice, and the “mytho-logics” of political violence. Specific attention is given to the symbolism of the time and space of terrorism, such as the symbolism of particular days, buildings, or public spaces.

Partly in response to this, others have argued that while terrorism is usually informed by strong convictions, it should also be understood in terms of inferior motives such as status, glamour, friendship, and money. Martha Crenshaw (1988) argues that terrorist groups can be analyzed as communities accommodating a variety of individual needs, such as the needs for recognition, excitement, and material benefits. The militant group is as much driven by the need to maintain itself as by its ideological objectives. These observations are used to argue that those militant groups whose existence is threatened by internal friction or outside aggression are usually the most violent. Others examine individual motives for joining a militant organization. Joseba Zulaika (1988) in a study on the ETA describes militant groups as the continuation of friendship in already existing peer groups. In a similar vein, recent terrorism has been explained as an attempt by religiously inspired militants to overcome existential anxieties caused by alienation, humiliation, and marginalization.

A growing body of work concerned with aspects of terrorism is the study of state terror. Michael Taussig (1984) has used the term cultures of terror to denote societies that are under constant threat of state violence and intimidation. This line of work focuses on the systematic use of torture and death squads, rumors, secret intelligence, and other forms of intimidation by state institutions, as well as on individual and collective coping strategies used by the victims of state terror. State terrorism can also include the deployment of terrorist actions by one state against another state, as shown, for example, by Libya's involvement in the explosion of Pan Am flight 103 over Lockerbie, Scotland, in 1988. In terms of numbers of victims, state terror is a much more serious problem than the terrorism of revolutionary or religiously inspired militants.

The study of terrorism-related discourse focuses on the use of the terrorism concept in the media, by policy makers, and by “terrorists” themselves. Studies on the “symbiotic relationship” between terrorists, the media, and state propaganda portray terrorist violence as “spectacle,” as “theater” and “performative,” or as “ritual.” Without denying the reality of death and destruction, these studies focus on how the media frames terrorism in terms of Good and Evil, leaving little room for anything other than one-dimensional conceptions of terrorism and counterterrorism. The way terrorism was reported during the cold war, for example, created a fear of totalitarianism and of incomprehensible technology. More recently, and especially since the attacks of September 11, 2001, terrorism discourse resonates with the fear of religious fanaticism. Most of these studies also trace the complex relations between the media and state policy. Governments often brand their enemies as “terrorists” in order to legitimize an excessive use of force and the violation of human rights. At the same time, the perpetrators of “terrorist” violence themselves evoke collective fears and fantasies associated with terrorism in an effort to become “larger than life.”

Following the September 11, 2001 attacks on the World Trade Center and the Pentagon, the study of terrorism has changed significantly, not only in quantitative terms, but also substantively. Book titles like Terror in the Mind of God (Juergensmeyer 2000) and Terror in the Name of God (Stern 2003) indicate an increased interest in the relationship between terrorism and religion. Studies of religious militancy largely fall into one of three categories. A culturalist approach tries to explain recent Islamist militancy in terms of long-standing traditions of violence and intolerance in Islam. A more empirical approach examines religious extremism per se, comparing Islamist militants with, for instance, American antibortionists and Zionist extremists. Rather than being rooted in age-old and supposedly unchanging traditions, recent religious militancy is said to draw inspiration from renewed and redefined notions of purity and holy war, fostered by anxieties and inequalities caused by globalization and political or social marginalization. A historical approach examines religious radicalism as political ideology and religious militant groups as political organizations. Such studies analyze the rise of Islamic radicalism, the history of Al-Qaeda, or the life of bin Laden against the backdrop of geopolitical developments in the Middle East and Asia since the 1980s. Gilles Kepel (2002), for instance, explains the “9-11” attacks by Al-Qaeda as a sign of disillusion and an attempt to reverse a process of decline after various failed attempts to retain political power for the Islamist ideology.

Post-“9-11” studies of terrorism not only center on religion, but also focus on the sites, the organization, and the methods of modern terrorism. Today's terrorism is often transnational in scope, objective, and organization, and transcends the boundaries of the nation-state. Stephen Graham (2004) studies modern terrorism explicitly as an urban phenomenon, exploring the ways in which terrorism and counterterrorism are shaped by, and transform, the public life of global cities. As for the study of terrorist organizations, the emphasis has shifted from cell-structured and network organizations to the “rhizomatic” character of transnational terrorism. Some of the best-known terrorist phenomena like Al-Qaeda are franchises, allowing loosely connected “freelancers” to operate

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 329
in their name, as much as they are organizations or networks. Finally, Walter Laqueur (1999), among others, in a book predating "9-11," explores the ways in which terrorist methods may evolve from the traditional methods of assassinations and hijacking to new forms of chemical, biological, nuclear, and cyber terrorism.

TERRORISTS

Terrorists are nonstate actors who pursue random unconventional violence targeted at noncombatants to achieve political objectives. The labeling of who is a terrorist depends heavily on who is making the distinction. President Ronald Reagan's observation that one man's terrorist is another man's freedom fighter implies the difficulty in objectively labeling certain people as terrorists. It is only nonstate actors who are defined as terrorists because according to current standards of international law, governments cannot engage in terrorism. Though some states support and even sponsor terrorism, acts of violence committed by states against noncombatants are considered by international law to be crimes against humanity or war crimes, not terrorism.

The term terrorist is pejorative, and implies that persons so-labeled are immoral, evil, and criminal. Whereas criminals are considered innocent until proven guilty in the judicial systems of many democratic countries, there is no defined legal threshold to prove someone is a terrorist. Rather, individuals or groups are identified as terrorists precisely because they are labeled as such, regardless of whether these individuals or groups have actually engaged in random violent actions against noncombatants. Therefore, the burden of proving guilt is not on the government as with nonpolitical criminals. Rather, the burden of proving innocence is on the individuals who are accused of pursuing terrorism. Because it is nearly impossible to prove innocence, governments tend to eagerly label anyone who could be linked to acts of violence as terrorists.

In fact, individuals who engage in violent actions deemed as terrorism often perceive and label themselves as freedom fighters, resistance fighters, soldiers of God, or liberators. They also perceive their actions as the best means available to achieve the political objectives of the group to which they belong. Terrorists do not perceive their actions to be illegitimate or immoral. Rather, terrorists often argue that they must pursue violent actions in order to provoke a response, primarily from the government of a state, because the status quo has prevented them from achieving their political objectives.

Besides the actual individuals who engage in or attempt violent acts, terrorists can also be members of a group that provides tactical support—planning, funding, training, and ordering violent acts. In order to be considered a terrorist, an individual must be a member of a group with some type of political agenda. Individuals acting without any political agenda are not considered terrorists, but rather murderers, kidnappers, or other types of criminals. Though terrorists can simultaneously be guerrillas, the two designations are distinct in that guerrillas are defined as those who deliberately target military targets rather than noncombatants.

Terrorists engage in violence that is criminal in nature and illegal in most countries. Typical violent acts pursued by terrorists include the use of explosives, suicide bombing, the hijacking of an airplane, kidnapping, and murder. Terrorist groups are inherently clandestine due to their need to stay below the radar of government officials seeking to eradicate such organizations. Because it is difficult to remain clandestine, terrorists often seek support and assistance from governments that support their political agenda or objectives. Therefore, many terrorist groups maintain training camps in countries such as Syria, Libya,
Sudan, and Iran, all of which have been known to provide support to terrorists. To prevent discovery, terrorists often use e-mail and temporary cell phones when communicating and false identification papers when traveling. Though all strategic and tactical planning is pursued clandestinely, the actual terrorist activities are by necessity pursued publically in order to draw mass attention and terrorize society.

The immediate objective of terrorists is to terrorize society by pursuing random violence, while the long-term objective is to persuade a government to change policies or take certain actions. Typical political objectives of terrorist groups include the release of political prisoners, improved political and civil rights, greater political autonomy, and territorial sovereignty.

Many terrorist groups are based in countries with governments that tend to be oppressive, repressive, intolerant of cultural diversity, and sometimes racist, denying political and civil rights to certain groups. As a result, terrorists and their supporters often argue that they have a legitimate right to resist such governments and to throw off the yoke of governmental persecution, just as many revolutions succeeded in doing in Western countries like the United States and France. Many non-Western governments are unwilling to label individuals seeking political freedom, sovereignty, rights, and so on as terrorists, and perceive their embrace of violence as exercising a right of resistance. This has led to a division between Western and non-Western governments and has prevented the United Nations from arriving at an agreed-upon definition of terrorism.

Governments seeking to eradicate or prevent future terrorism and to prosecute terrorists have created extensive counterterrorism policies. Such policies include the sanctioning of states suspected of supporting and hosting terrorist groups; arresting and trying individuals suspected of direct or indirect involvement in activities deemed terrorist; the collection of intelligence internationally and domestically, through monitoring communication, spying, using informants, and so on; increasing security at transportation hubs and government buildings; and sometimes even assassinating suspected terrorists. Though governments spend significant sums of money on counterterrorism efforts, terrorism continues to increase as the political objectives of terrorists expand. As a result, some governments are willing to address such political objectives in order to prevent future terrorist attacks.

TEST STATISTICS

Hypothesis testing or significance testing is undoubtedly one of the most widely used quantitative methodologies in empirical research in the social sciences. It is one viable way to use statistics to examine a hypothesis in light of observations or sample information. The starting point of hypothesis testing is specifying the hypothesis to be tested, called the null hypothesis. Then a test statistic is chosen to summarize the sample information, and its value is taken as an indication of the strength of sample evidence against the null hypothesis.

Modern hypothesis testing dates to the 1920s and the work of Ronald Aylmer Fisher (1890–1962) on the one hand, and Jerzy Neyman (1894–1981) and Egon Pearson (1895–1980) on the other. Fisher (1925) refers to hypothesis testing as significance testing (this entry does not distinguish between the two terms). In the Fisherian approach, the observed test statistic is converted to the P-value, which is the probability of obtaining the observed or more extreme value of the test statistic under the null model; the smaller the P-value, the stronger the sample evidence against the null hypothesis. An early example of Fisher’s significance testing was conducted in 1735 by the father and son Swiss mathematicians Daniel Bernoulli (1700–1782) and John Bernoulli (1667–1748). They tested for the random/uniform distribution of the inclinations of the planetary orbits. A detailed discussion of their original results and subsequent modifications of their results can be found in Anders Hald (1998).

In the Neyman and Pearsonian (1928, 1933) approach, an alternative hypothesis is specified and the null hypothesis is tested against this alternative hypothesis. The specification of an alternative hypothesis allows the computation of the probabilities of two types of error: Type I error (the error of falsely rejecting a null hypothesis) and Type II error (the error of incorrectly accepting a null hypothesis).
Type I error is also referred to as the significance level of the test, and one minus Type II error the power of the test. Given that the two types of error cannot be minimized simultaneously, the common practice is to specify the level of significance or Type I error and then use a test that maximizes its power subject to the given significance level. In the Fisherian approach, the $P$-value is reported without necessarily announcing the rejection or nonrejection of the null hypothesis, whereas in the Neyman and Pearsonian approach, the null hypothesis is either rejected in favor of the alternative hypothesis or not rejected at the given significance level. E. L. Lehmann (1993) provides a more detailed comparison of the two approaches.

In empirical research, a mixture of the two approaches is typically adopted. Consider the linear regression model:

$$Y_i = \beta_1 + \beta_2 X_{i2} + \beta_3 X_{i3} + \cdots + \beta_K X_{iK} + \varepsilon_i, \quad i = 1, \ldots, n$$

(1)

where $\{Y_i, X_{i2}, \ldots, X_{iK}\}$ is the set of observations on the dependent variable $Y$ and the explanatory variables $X_{i2}, \ldots, X_{iK}$, and $\varepsilon_i$ is the unobserved error term. The parameters $\beta_2, \ldots, \beta_K$ measure the ceteris paribus effects of the explanatory variables on the dependent variable. The significance of these effects is routinely tested by the t-tests and F-test. The t-test was discovered by William Sealy Gosset (1876–1937) for the mean of a normal population and extended by Fisher in 1925 to other contexts, including regression coefficients. Gosset’s result was published in Biometrika under the pseudonym “Student” in 1908. The F-test was originally developed by Fisher in the context of testing the ratio of two variances. Fisher pointed out many other applications of the F-test, including the significance of the complete regression model.

For a given $j = 2, \ldots, K$, the null hypothesis for the corresponding t-test is $H_{0j}: \beta_j = 0$ and the t-statistic is

$$t_j = \frac{b_j}{se(b_j)}$$

where $b_j$ denotes the ordinary least squares estimator of $\beta_j$ and $se(b_j)$ denotes the standard error of $b_j$. Note that if the null $H_{0j}$ is true, the explanatory variable $X_j$ would be absent from the regression model (1) and thus considered to be insignificant in explaining the dependent variable given the presence of the other explanatory variables. This is why t-tests are referred to as tests for the significance of individual variables as opposed to the F-test, which tests for the significance of the complete regression. The null hypothesis for the F-test is

$$H_0: \beta_2 = \beta_3 = \cdots = \beta_K = 0.$$  

There are several equivalent formulas for computing the F-statistic, one of which is

$$F = \frac{R^2/(K - 1)}{(1 - R^2)/(n - K)},$$

where $R^2$ is the coefficient of determination. Since under $H_{0j}$ all the explanatory variables can be dropped from (1), the F-test is a test for the significance of the complete regression.

Much packaged computer software routinely calculates the t-statistics and the F-statistic. For a given sample, the observed value of $t_j (F)$ summarizes the sample evidence on the significance of the explanatory variable $X_j$ (the significance of the regression (1)). To either convert the observed value of $t_j (F)$ to the $P$-value or make a binary decision on the rejection or nonrejection of the null hypothesis $H_{0j} (H_j)$ at a given significance level, the distribution of $t_j (F)$ under the corresponding null hypothesis is required. On the basis of the null hypothesis being true and further assumptions on the nature of the sample and on the normality of the error in (1), the distribution of $t_j$ is known to be Student’s t with $(K - 1)$ degrees of freedom, denoted as $t_{(K - 1)}$, and the distribution of $F$ is the so-called F-distribution with $(K - 1), (n - K)$ degrees of freedom denoted as $F_{(K - 1), (n - K)}$ (see Goldberger [1991] for details). The known distribution of $t_j (F)$ under the null hypothesis allows the computation of the $P$-value or the computation of the appropriate critical value at a prespecified significance level with which the observed test statistic can be compared.

Like t-tests and the F-test, standard tests rely on further assumptions in addition to the truth of the null hypothesis, such as the assumption of a random sample and the normality of the error term. These further assumptions may not be met in typical applications in social sciences, and modifications are required of tests designed on the basis of these assumptions. For example, when normality of the error term is not met, the distributions of the t-statistic and F-statistic are no longer $t_{(K - 1)}$ or $F_{(K - 1), (n - K)}$. Fortunately, their asymptotic distributions are known under general conditions and may be used to perform these tests. Alternatively, resampling techniques, such as the bootstrap and subsampling, may be used to approximate the distributions of the test statistics under the null hypothesis (see Efron and Tibshirani [1993] and Politis et al. [1999] for an excellent introduction to these methods).

The issue that has generated the most debate in hypothesis testing from the beginning is the choice of significance level (Henkel 1976). Given any value of the test statistic, one can always force nonrejection by specifying a low enough significance level or force rejection by choos-
ing a high enough significance level. Although reporting the $P$-value partly alleviates this arbitrariness in setting the significance level, it is desirable to report estimates of the parameters of interest and their standard errors or confidence intervals so that the likely values of the unknown parameters and the precision of their estimates can be assessed.

**TEXTILE INDUSTRY**

The textile industry is the world’s oldest branch of consumer goods manufacturing and covers the entire production chain of transforming natural and chemical fibers (such as cotton, wool, and oil) into end-user goods, including garments, household goods, and industrial textiles. In the twelfth century China already produced cotton and fabrics. In the early seventeenth century India and Japan had domestic cotton industries. Modern textile manufacturing originated in Great Britain during the Industrial Revolution around 1780. The mechanization of spinning and weaving alongside a rising demand for clothing from the colonies contributed to the growth of “king cotton.” In the early nineteenth century textile production spread from Britain over western Europe and the United States. Ever since that time, the textile industry has been one of the most competitive and geographically dispersed industries across the world.

Accounting for 5.6 percent of world trade flows and employing at least twenty million workers worldwide, the modern textile industry is a significant economic sector. Despite its geographical dispersion, large concentrations of textile production can be found in China, followed by India, the United States, the Russian Federation, Japan, and western Europe. Since the 1970s a gradual shift of production has taken place to newly industrializing countries in East and Southeast Asia, Latin America, eastern Europe, and North Africa.

The textile industry is typically the leading sector of industrialization. Usually, textiles manufacturing is labor intensive and employs relatively low skills and simple technologies. Moreover, the capital investment needed is only modest in comparison with other types of industry. Some developing countries also benefit from local supplies of raw materials (e.g., cotton) that foster the development of textiles production. Thanks to low labor costs, the newly industrializing countries have become fierce competitors for producers in Europe and North America. This rivalry, combined with saturated home markets, has induced corporate restructuring in the European Union and the United States, making the textile industry progressively an industry of large, transnational corporations.

Growing competitive pressure has led to a variety of corporate strategies in American and European textiles. Some companies attempt to cut costs by producing standardized goods that benefit from economies of scale. Other firms pursue offshore strategies and relocate part of their operations to low-labor-cost countries. Most producers, however, choose for focused differentiation: They search for market niches where specialized goods can be sold for a premium price. For that purpose many textile firms invest in quality improvement, innovation, design, marketing, and retailing. Some of the firms also focus on the production of technical textiles (e.g., artificial grass). All these differentiation strategies ask for sophisticated skills, knowledge of local markets, and flexible production facilities. Textile firms increasingly have to cope with a trade-off between labor costs and the need for market proximity.

Since the 1960s, governments in western Europe and America have protected domestic textile producers by means of trade arrangements. After the Long-Term Arrangement in 1962, the Multi-Fibre Agreement was negotiated in 1973. The aim of both agreements was to create an “orderly” development of global textiles trade—not only for developed but also for developing coun-
tries—by restricting imports that “disrupted” domestic markets. In practice merely the European and North American nations profited from the rules, because in most cases the cheap exports from developing countries were considered to be disruptive for the matured textile industry in the developed world. However, thanks to World Trade Organization (WTO) rules, which aim for nondiscrimination between all trading partners, and following a ten-year transition period (1995–2004), the global textile industry is liberalizing more and more. The protectionist strategies of older, established textile nations and the lack of attention of transnational firms for good labor and environmental circumstances at offshore locations are often criticized. Further liberalization should contribute to an improvement of these conditions in the textile industry across the globe.

THANT, U.

1909–1974

Thant’s ten years as UN secretary-general unfolded within the context of a continuing cold war rivalry between the United States and Soviet Union and the emergence onto the world scene of scores of newly independent states, drawn primarily from Africa and Asia. He managed during his two terms to secure the legitimacy of the position of secretary-general, which had come under assault from the Soviet Union during the last year of Hammarskjöld’s life, but he did little to expand the powers of the office. He proved himself a vigorous advocate for the economic concerns of third world nations and a vocal opponent of colonialism in southern Africa, but when he left office, in December 1971, the inequitable distribution of global wealth and continuing colonial situations in South Africa, Rhodesia, Namibia, and Angola remained as intractable as ever.

Thant’s early years in office found him working in cooperation with the United States to quell a secession in the Congo and to fashion major peacekeeping initiatives in West New Guinea, Yemen, Malaysia, Cyprus, and Kashmir. His role as diplomatic facilitator during the Cuban missile crisis of 1962, although modest, earned him the respect of both superpowers and an extended first term as secretary-general. However, by the time of his reappointment to a second term, in 1966, Thant was expressing increasing frustration with his role. The UN’s effectiveness was threatened by the refusal of the Soviet Union and France to contribute to peacekeeping operations. The fiscal crisis that emerged escalated into a political crisis when the United States, invoking Article 19 of the UN Charter, sought unsuccessfully to deny the Soviets a vote in the General Assembly. Further frustrating Thant was his inability to broker an end to the Vietnam War (1957–1975), despite his publicly voiced opposition to the American war effort.

Thant’s last years in office were characterized by renewed frustrations. In 1967 he quickly surrendered to Egyptian demands that he remove UNEF (United Nations Emergency Force) from Egypt’s border with Israel, thus earning widespread blame for the ensuing Arab-Israeli war. In 1971 the United Nations and Thant stood by helplessly as insurrection in the eastern part of Pakistan led to war between Pakistan and India and the dismemberment of Pakistan. Although pressed to assume a third term, Thant retired from office in December 1971.

Thant died on November 25, 1974. Denied a state funeral by the military junta that had ousted U. Nu in 1962, Thant’s body was seized by antigovernment students who buried him, with full honors, at Rangoon University and used the occasion to stage antigovernment demonstrations. Government forces reclaimed Thant’s body in a bloody confrontation with the student protesters and buried him near a major Buddhist pagoda in Rangoon.

THATCHER, MARGARET
1925–

Margaret Thatcher’s political career was marked by a series of “firsts.” In June 1979 she became the first female prime minister of the United Kingdom. She was the first U.K. prime minister in the twentieth century to win three consecutive general elections (1979, 1983, and 1987), and upon her resignation in November 1990, she had become Britain’s longest continuously serving prime minister since 1827.

Thatcher was also unique in having her name associated with a set of ideas, policies, and style of governance known as Thatcherism. Yet the extent to which Thatcherism as an ideology guided the policies of Thatcher’s governments in office has been disputed. What is not in dispute is that these policies fundamentally altered the trajectory of the United Kingdom’s economy, society, and polity and continued to impact upon policy outputs, political discourse, and electoral competition long after the demise of the Thatcher government.

Thatcherite economic policies were broadly labeled monetarist even though, technically, a monetarist strategy was only pursued for a limited initial period. In an attempt to reverse Britain’s long-term economic decline, Thatcher challenged the basis of the postwar Keynesian social democratic consensus by attempting to restructure patterns of property ownership, taxation, and social attitudes toward welfare. An ambitious program of privatization transferred major state-owned industries and public services into the private sector, and 1.5 million public-sector houses were sold to their tenants. A parallel program of marketization promoted the use of market criteria by public-sector service providers—especially local authorities and the National Health Service. Taxation policies sought to reward “initiative” and “enterprise” through reduced rates of income tax. In parallel, welfare and social benefits were restructured, reduced, and increasingly means tested; and social attitudes toward collective welfare provision were challenged, most famously in Thatcher’s phrase “there is no such thing as society” (from an interview with Douglas Keay, 1987).

A hallmark of Thatcher’s period in office was her style of governance. She confronted most of the powerful social and political institutions in the United Kingdom. Major state institutions—most particularly the civil service and local government—were reformed, and a wide range of regulatory bodies was introduced. A “community charge” (known as the poll tax) was imposed to reform the system of local government financing. This tax was extremely unpopular and prompted widespread nonpayment and, ultimately, riots in London in November 1990. The legal position and standing of trade unions was altered radically by five major legislative acts. Thatcher’s foreign policies also revealed her combative nature. Her condemnation of Soviet-style communism earned her the epithet “the Iron Lady” in the Soviet press. Her support for Ronald Reagan (1911–2004), and for a close relationship with the United States, was reflected in mutual transatlantic perspectives on the cold war. Her general hostility to further European integration and her specific resistance to the creation of a federal European Union earned the United Kingdom the title “the awkward partner.” However, the Falklands War, waged in 1982 against Argentina, secured Thatcher’s status as a “warrior queen” in the popular press in the United Kingdom. The war lasted for seventy-four days, between April and June, and ended when British troops successfully reclaimed the British dependency of the Falkland Islands in the South Atlantic after an invasion by Argentina. Thatcher’s image as a decisive war leader strengthened her poll ratings and was emphasized successfully in the Conservative Party’s 1983 election slogan “the resolute approach.”

After her resignation in 1990, Thatcher remained a member of Parliament until the 1992 general election. Thereafter she joined the House of Lords as Baroness Thatcher, and after a series of strokes she retired from public speaking in 2002. However, the legacy of Thatcher was profound, not least because of her impact upon her political opponents. Indeed the policies pursued by the Labour Party under Tony Blair were variously described as sub-Thatcherite, neo-Thatcherite, or simply Thatcherite.

THEATER
Contemporary British director Peter Brook wrote of theater and its essence in his book, *The Empty Space* (1968), “A man walks across this empty space (a bare stage) whilst someone else is watching him, and this is all that is needed for an act of theater to be engaged” (p. 9). By Brook's reckoning, the actor, the stage space, and the audience are the minimal necessary components for the art of the theater. At its most basic level, theater is a story presented in public by a performer or performers, for an audience.

There exists a distinction between the related art forms of drama (the written text) and theater (the process of performing the written text within a designated space). A difference must also be drawn between theater as a form of artistic or cultural entertainment and the existence of theatrical components within a culture. Performance occurs regularly in daily life (e.g., sporting events, political campaigns, weddings, and other social rituals), but these are not considered theater in the strictest sense. These routine presentations form the basis of performance studies, a discipline that uses terminology from the theater and that of anthropology in an effort to analyze how it is interpreted for a contemporary audience. A theatrical form (e.g., comedy or tragedy) is a specific identifying plot structure as it demonstrates typical themes of human experience. A theatrical style (e.g., Shakespearean or expressionistic) is the representative interpretation of a form, based on audience expectations determined by place and time. Style may be associated with a specific historical period, playwright, culture, or artistic movement, whereas form is more universal and changes little from one culture to another.

The four distinct dramatic forms are: tragedy, comedy, drama, and mixed-forms. Tragedy concerns the fate of a main character who is caught up in events beyond his or her control, and is subsequently ruined as a consequence of a moral weakness or an inability to cope with difficult circumstances. Comedy—be it satire or farce—requires the happy or ironic resolution of a conflict involving an individual or a community. Aristotle wrote in his *Poetics* that the main difference between the tragedy form and the comedy form is that “one imitates people better, the other one people worse, than the average” (1967, p. 18). Tragedy and comedy were the dominant forms of theater until the eighteenth century. The form of drama emphasizes the moral seriousness of social issues, often through depictions of characters and situations drawn from daily life. Eighteenth-century French dramatic theorist Denis Diderot (1713–1784) advocated in his described theater (or drama) as an imitation of men in action. Theater is an artistic form that lends itself easily to critiques of social problems, heralding the possible transformation of society in the wake of a public performance expressing new ideas for change.

One explanation for theater’s origins lay in the ceremonial rituals of primitive cultures, usually linked to religious worship. Storytelling is an alternative explanation for theatrical origins, a performance in which a narrator such as a tribal leader or shaman recalled episodes important to the history of the tribe, acting out the events while interpreting the different characters for the shared enjoyment of the audience. The theatrical ritual achieved greater aesthetic sophistication as the cultures advanced, utilizing multiple actors, spectacle, dance, music, and costuming in an effort to make the performances more enjoyable. Society eventually began to prize these performances as much for their inherent entertainment and artistic values, as for their ritual significance.

FORM AND STYLE
Theater has developed different approaches to the creation of dramatic structure, utilizing a multitude of various styles and performance traditions. The play’s form is the clearly identifiable organization of the plot elements, while the play’s style is the means by which the form is interpreted for a contemporary audience. A theatrical form (e.g., comedy or tragedy) is a specific identifying plot structure as it demonstrates typical themes of human experience. A theatrical style (e.g., Shakespearean or expressionistic) is the representative interpretation of a form, based on audience expectations determined by place and time. Style may be associated with a specific historical period, playwright, culture, or artistic movement, whereas form is more universal and changes little from one culture to another.

The four distinct dramatic forms are: tragedy, comedy, drama, and mixed-forms. Tragedy concerns the fate of a main character who is caught up in events beyond his or her control, and is subsequently ruined as a consequence of a moral weakness or an inability to cope with difficult circumstances. Comedy—be it satire or farce—requires the happy or ironic resolution of a conflict involving an individual or a community. Aristotle wrote in his *Poetics* that the main difference between the tragedy form and the comedy form is that “one imitates people better, the other one people worse, than the average” (1967, p. 18). Tragedy and comedy were the dominant forms of theater until the eighteenth century. The form of drama emphasizes the moral seriousness of social issues, often through depictions of characters and situations drawn from daily life. Eighteenth-century French dramatic theorist Denis Diderot (1713–1784) advocated in his

Encyclopedia (c. 1755–1780) that this new drama “will encourage the light of reason, which everywhere grows brighter … and the spirit of the century will advance the revolution it began” (1967, p. 91). A mixed-form dramatic text combines elements of the comedy and tragedy forms and is a very uncommon form of theater. Theatrical styles, on the other hand, are many in number. Each style is associated with a specific time period (e.g., Restoration comedy such as William Congreve’s *The Way of the World*), author (e.g., Shakespearean tragedy like *Hamlet*), or artistic movement (e.g., realistic drama, as an example Anton Chekhov’s *The Cherry Orchard*).

**HISTORY**

Although the essential nature of theater is constant, the theatrical art form developed differently during various historical periods and throughout the regions of the world. Eastern (Asian) theater traditions predate Western (European) theater and utilize vastly different conventions (i.e., agreed-upon performance techniques). Asian theater forms rely heavily on the elements of musical performance and bodily expression to relate the story line to the audience. Chinese theatrical forms were first recorded in 1767 BCE during the Shang Dynasty. Popular entertainments of the time included shadow-play and puppet theaters, and live entertainers often performed at teahouses. Chinese theater was performed on a bare stage, accompanied by music, and characterized by a strict adherence to traditions. The most prolific contemporary expression of Chinese theater is the *Beijing Opera*, which employs a strictly ordered system of dance, singing, and acting to enhance the performance. Indian theater dates from the first century CE, and included Sanskrit dramas in which Indian actors performed specific codified gestures and chanted intonations with musical accompaniment designed to cultivate a balanced aesthetic, emotional state called a *rasa* within the spectators. Formal Japanese theater dates from the sixth century CE and includes variations such as Noh theater (1374), a stylized musical dance-drama with choreographed movements and masks; Bunraki theater (early seventeenth century), a puppet theater; and Kabuki theater (1603)—the most popular form—in which dance and spoken dialogue are used in conjunction with sets, stylized make-up, and costuming, to achieve the desired theatrical effect.

The formal Western theater tradition began in Greece with the ritual worship of Dionysus, the God of wine and revelry. The word *tragedy* evolved from the Greek word *tragoidia* (goat-song), the performance that accompanied ceremonies of ritual animal sacrifice. In 534 BCE, the city of Athens organized a contest to determine the best tragedy during the religious festival of the City Dionysia. At the festival, tragedies were performed in sets of three linked stories drawn from either history or myth, followed by a satyr play (a short farcical comedy utilizing burlesque). Comedies were introduced at the City Dionysia after 487 BCE. The earliest Greek theaters were temporary wooden structures built into hillsides. Permanent theaters made of stone began to appear in the fourth century and were capable of seating more than ten thousand spectators. Greek actors performed on a small circular area called the *orkestra* (dancing place), which featured a *thyrsome* (small altar) for the ritual sacrifice, surrounded by the risers of the audience area, called the *theatron* (seeing place). The first *skene* (small scenic house) appeared in 458 BCE. The fifth century is recognized as the Golden Age of Greek Theater, with more than one thousand different plays believed to have been performed. Only thirty-one tragedies survive from the period—all written by three playwrights: Aeschylus (525–456 BCE), Sophocles (c. 496–406 BCE), and Euripides (c. 484–406 BCE). The Athenian playwright Aristophanes (c. 450–c. 388 BCE) is the only comic playwright of the time whose works have survived. Greek tragedies were written originally for just two actors, but in 468 BCE the use of a third actor was established. Each actor would play multiple roles, indicated by distinctive masks and representative props. Greek dramas also were the first to feature the chorus, a group of performers who chanted rhythmically, danced, and commented on the course of the action in the play.

Greek theater was appropriated by the Romans after 240 BCE but eventually gave way to more popular forms of entertainment. Roman citizens preferred spectacular and bloody events such as chariot races, armed contests between gladiators, wild animal fights, and mock naval battles (often staged in flooded amphitheaters). The rise of the Christian Church in the fourth century CE signaled a fierce opposition to theatrical practices, due to their origins in pagan rituals and their licentious subject matter. Organized theater all but disappeared by the sixth century, following the fall of Rome to the Visigoths, though some entertainment forms such as mimes, minstrels, and festivals continued in local communities until the Middle Ages and the re-emergence of theater as an art form. Liturgical dramas were performed during church services as a means of imparting religious doctrine to illiterate parishioners. The earliest recorded liturgical drama occurred during an Easter service around 925 CE, and included monks performing the discovery at the tomb. Plays moved out-of-doors and became part of religious festivals after 1300 CE, with performances staged on small, movable structures known as mansions. Local trade guilds took over the staging and financing of cycle plays (a group of plays featuring biblical story interpretations). Local vernacular language eventually replaced Latin as the spoken language of the performances, which also began to feature more secular subjects.
Religious strife and internal church conflicts changed the face of Europe in the fourteenth through sixteenth centuries. Religious theater was eventually outlawed, and entertainments began to be provided by a new professional theater during the Renaissance. Permanent theaters blossomed in London during the late sixteenth century and were staffed by acting troupes maintained by wealthy noblemen. The performances had a broad and popular appeal and were attended by the titled and commoners alike. The most famous English playwright of the period was William Shakespeare (1564–1616), who is believed to have penned an estimated thirty-eight plays. The English Civil War closed the London theaters in 1642. Meanwhile, opera emerged in Italy as a popular Renaissance form and prompted innovations such as scenic stage sets incorporating perspective drawing, machinery for changing background scenery in view of the audience, and rigging created for the purpose of flying people and scenic pieces around the stage. A new style called neo-classicism emerged in France during the sixteenth and seventeenth centuries, in which drama was made to conform to critical principles based on contemporaneous interpretations of classical theater. Most important were the unities of time, place, and action (each play should have a single plot action that could occur within a twenty-four-hour period and in locations that could realistically be reached during a single day of travel). Neoclassicism also demanded that the characters practice decorum (behaving according to strictly established social etiquette) and was centered on the notion of verisimilitude (the appearance of truth).

This preoccupation with realistic action/behavior onstage foreshadowed the early nineteenth-century development of romanticism. Romanticism was a revolt against the rules of the neoclassical theater and featured plotlines inclined toward emotional truth rather than rational knowledge and characters drawn from the lower social classes rather than the nobility. Romanticism flourished through the 1850s, followed at the end of the century by realism. Realism was the result of two modes of intellectual thought: The first involved the application of scientific thought to theatrical life, resulting in lifelike portrayals; while the second mode centered on democratic political ideals precipitating the need for social transformation. Theater was viewed as a laboratory of humanity, a place to test new ideas of social behavior and reform. The theater of the period exposed contemporary social ills (such as the plight of women in The Doll's House, the best known of Norwegian playwright Henrik Ibsen's realistic works), and made suggestions for reform (freedom from outmoded social structures). The director emerged as an artistic force during this period, bringing creative and visual unity to the stage performance. Also important during the late nineteenth century was the origination of musical theater (which uses song, dance, music, and spoken dialogue to relate a story). Musical theater remains one of the most popular entertainments into the twentieth and twenty-first centuries.

**TWENTIETH-CENTURY THEATER**

The avant-garde theater (also known as anti-realistic theater) was a strong presence in the early twentieth century, as writers and performers rejected realism and tried to reinvent the ideas of what constituted art. Avant-garde art pushed the boundaries of what is accepted as real, while at the same time attempting to document an individual's perceptions of reality. Twentieth-century avant-garde theater styles include expressionism, futurism, dadaism, and surrealism. Absurdism (life cannot be logically explained) is a style of the avant-garde that became very influential in theater following World War II. This eventually led to a backlash of radical experimental theater in the 1960s, meant to mingle political significance with aesthetic creation. This experimentation laid the groundwork for the contemporary post-modernist movement, which signals a break with the modernist movement and traditional portrayals of experience. Post-modernism theater utilizes a mixture of styles and advocates the primacy of the audience response to the formation of the work. Despite this growth and evolution of alternative styles, however, realism and musical theater remain the dominant mainstream theater fare of the twentieth and early twenty-first centuries.

THEIL, HENRI
SEE Theil Index.

THEIL INDEX

The Theil index, named for Dutch econometrician Henri Theil (1924–2000), is a special case of the family of inequality measures called the Generalized Entropy Measures. In its aggregate form, the Theil index is a measure of overall inequality. In addition, it lends itself to additive decomposability, a property that is extremely useful for simultaneously examining three aspects of inequality in a society divided into mutually exclusive and completely exhaustive social groups (e.g., based on gender, caste, race, religion, and so forth). Economists have used the decomposed version of the Theil index effectively to identify and highlight important sources of inequality in a given population. (e.g., Mookherjee and Shorrocks 1982; Conceição and Galbraith 2000). While this exercise is indeed efficacious, it is important to bear in mind that this is essentially an ex-post accounting of inequality as constituted by intergroup and intragroup inequalities, rather than a statement of causation.

With the assumption that individuals are grouped into $m$ mutually exclusive and completely exhaustive groups $g_1, \ldots, g_m$, each with $n_i$ individuals, overall inequality can be represented as follows:

$$T = \sum_{j=1}^{m} p_j R_j \log R_j + \sum_{j=1}^{m} p_j R_j T_j$$  \hspace{1cm} (1)$$

$$T_j = \frac{1}{n_j} \sum_{i \in g_j} r_i \log r_i$$  \hspace{1cm} (2)$$

The decomposed version as stated above has two components that are interpreted below. However, it should be noted that inequality measures, such as those in equations (1) and (2), can be defined with respect to any number of classifications. For instance, Pan Yotopoulos and Jeffrey Nugent (1976) report Fisher’s index with respect to income classes $i$, sector $j$, educational attainment $k$, age $m$, and region $n$. The number of terms in the equation will be equal to the number of levels of stratification considered. For instance, in the expression above, the number of levels is two: society divided into groups, and groups comprising individuals. Fisher’s index will accordingly have five levels of stratification.

These equations can be interpreted in multiple ways. For instance, William Darity and Ashwini Deshpande (2000) have interpreted these equations differently from Pedro Conceição and James Galbraith (2000). In both interpretations, $T$ is treated as a measure of the general degree of inequality in a society or country, but the former characterization of the right side of the equation differs from the latter. The first term on the right hand side of (1) represents the extent of between-group inequality ($B$) across all ethnic groups in the population of focus. $R_j$ is the ratio of the mean income for the $j$th group to the mean income for the entire population, while $p_j$ is the $j$th group’s population share. The second term represents the extent of within-group inequality ($W$) across all ethnic groups in the population. $R$ and $p$ have the same definition, but $T_j$ is the group-specific Theil index measure, defined in (2). Here $n_j$ is the absolute number of persons in group $j$. $i \in g_j$ indicates that $T_j$ is generated by summing over all persons comprising group $j$, and $r_i$ is the ratio of individual income or wealth to mean income or wealth for group $j$.

Conceição and Galbraith compute the between-group component of Theil’s $T$ from wage or earnings data aggregated by industrial sectors in a very large number of countries, and by lopping off the within-industry component of wage variation in Theil’s $T$; they arrive at a lower bound estimate of dispersion (Conceição and Galbraith 2000). Darity and Deshpande, instead of focusing on industrial variations in compensation, consider the Theil’s $T$ from the perspective of variations in income or earnings across the major racial and ethnic groups that comprise a given society. They also presume that the identity of the groups is understood within the norms and conventions of the society in question. Note that under this interpretation, the weights in the Theil index virtually compel us to think of subaltern groups as minorities, or at most, modest majorities. Certainly, the interpretative validity becomes cloudy when the subaltern group is a substantial majority, as in South Africa.

The relationship between these three components is of more than just academic interest. The conventional interpretation of this equation would read it from left to right, where overall inequality would be the factor in exacerbating intergroup and intragroup inequality. However, Darity and Deshpande (2000) argue that the right-to-left
reading can be equally important. Thus, $B$ and $W$ can actually drive overall inequality, or, more broadly, group affiliation and allegiance are independently salient in explaining overall inequality. Seen this way, any analysis of overall inequality will be necessarily incomplete without reference to $B$ and $W$. However, given the caveat mentioned above, namely, that this is an ex-post accounting of overall inequality, the decomposed version of the Theil index cannot be used as a basis for inferring any kind of causation. Estimation over time is important to give clues about the relative contribution of $B$ and $W$ to a change in overall inequality. Darity and Deshpande raise the following questions suggested by this construction of the Theil index: Is it group difference or the general level of stratification across a population that is more decisive in shaping economic disparity? Does a higher degree of intergroup inequality necessarily produce greater levels of general inequality, or is the higher level of intergroup inequality mitigated by lower levels of within-group inequality? Does a higher level of general economic inequality produce greater levels of intergroup inequality?

The calculated values of individual components of $B$ and $W$ in equation (1) above need to be interpreted with care. Given that the mean incomes of the subaltern groups will necessarily be less than the overall mean incomes, the $B$s will be less than unity. Thus, the logs will be negative, and that, by construction, will make the overall $B$ less than the overall $W$. Numerically, this will imply that the relative contribution of $B$ to overall inequality will be substantially less than that of $W$ (Paul [1999] finds the same for Australian household expenditure survey data). Before drawing the prima facie inference that $W$ matters more than $B$, it would be good to remember that this outcome is a consequence of the construction of the index, and does not necessarily reflect the relative importance of $B$ and $W$.

**THEISM**

The Greek word *theos* means “god” or “divine power.” Hence, *theism* is the belief in a god, or the view that there is a god. Generally, theists think of *god* as a very powerful, personlike being who has control over some or all of the natural universe. To say that a god is personlike is to say that god is capable of thinking, acting, and communicating with other persons, especially human beings. Hence, theists typically refer to god by using pronouns such as “he” or “she” rather than “it.” Theists believe that god has a personality, that is, a set of character attributes or traits in accord with which god acts. To varying degrees, theists think of god as interested in some or all of the affairs of human beings.

Theism may be contrasted with *atheism*, *deism*, and *agnosticism*. Atheism is the belief that there is no god. Deism is the belief in a very powerful being who created or designed the world but who is not concerned with the affairs of human beings. Deists tend to conceive of this being as an impersonal force. Agnosticism is the view that one cannot know whether there is a god. Some agnostics hold that it is in principle impossible ever to know whether or not there is a god; others hold more provisionally that it is currently impossible to tell whether there is a god.

There are various forms of theism. *Polytheism* is the belief in more than one or many gods. *Monotheism* is the belief in one god, usually capitalized as “God” and used as proper noun to refer to this one being. This convention is used in the discussion that follows.

Many people in the ancient world were polytheists. Polytheists developed elaborate belief systems according to which there are many gods who rule over different parts of nature. Often, one god is thought to be the supreme ruler, such as Zeus for the ancient Greeks or Jupiter for the Romans. In some cases, a human king or emperor could be identified as a god himself. Polytheists tend to understand the gods as imperfect in both their power and moral qualities. The gods are not in complete control of nature or themselves, and they do not always act with moral consistency. They are not interested in all the affairs of...
mankind, but they do intervene on occasion, especially if propitiated by worship and devotion. A hallmark of polytheism is the practice of representing the gods in the form of idols or graven images, which are then used in the context of ritual worship.

The most populous form of polytheism in the world is a certain form of Hinduism. However, at least one form of Hinduism (articulated by Ramanuja in the eleventh century) is monotheistic. If the traditional Hindu gods are viewed as ultimate and independent entities, Hinduism is polytheistic; if the gods are viewed as outward manifestations of one underlying, personlike reality, Hinduism is monotheistic. Buddhism is generally polytheistic, but some forms of Buddhism, such as Zen Buddhism, are usually understood to be atheistic. If the gods are viewed as ultimate powers, Buddhism is polytheistic; if the gods are considered illusory or unreal, Buddhism is atheistic. Aside from Hinduism and Buddhism, many other forms of polytheism are still found elsewhere, such as in sub-Saharan Africa and among Native Americans.

While polytheists tend to understand the gods as limited and imperfect, monotheists tend to understand the one God as unlimited and perfect. Many monotheists think of God as all-powerful, all-knowing, and all good. God is thought to be the creator, king, and judge of the universe. Generally, monotheists believe that God has made certain demands on all humans, and that God directs human history with providence toward some great cosmic end.

Judaism, Christianity, and Islam are the most well known forms of monotheism. In Judaism and Islam, God is conceived as not having bodily form. Linked with this view is a strict ban on any representation of God in the form of an idol and a ban on any form of idol worship. Although the sacred scriptures in these two traditions use bodily language to describe God, these are generally interpreted as metaphors. In Christianity, the oneness and nonmateriality of God is complicated by the belief in the divinity of Jesus, who is understood by traditional Christians to be both divine and human. Traditional Christians maintain that in some sense God is a nonmaterial being who became incarnate in the person of Jesus. Others tend to view the incarnation less literally.

For theists, the highest purpose in life is for humans to develop an interpersonal relationship with God. Precisely what form that relationship takes and how one goes about attaining that relationship differ from one tradition to another. In Judaism, the most intimate relationship with God is found through the observance of the commandments of the Torah, which Jews believe to be God’s revealed teaching to the people of Israel. In Christianity, the most intimate relationship is found through good works and through faith in Jesus as the manifestation of God. In Islam, the best relationship is found through submission to God and obedience to divine law as expressed in the Qur’an, which Muslims believe to be the revelation of God’s word to the prophet Muhammad. All three forms of theism teach that respect or love for one’s fellows is part and parcel of respect and love for God. At the same time, these forms of theism traditionally teach that those who reject God or his commandments are in some sense deserving of punishment.

Over the centuries, philosophers, theologians, and others have debated whether it is rational to believe in God. Some insist that belief in God is not supposed to be rational; it is a matter of “faith.” Others argue that it is rational to believe in God. The most popular arguments for monotheism are based on the existence and orderly nature of the cosmos, on the phenomenon of religious experience or revelation, and on purported miracles. Some have argued that it is rational to believe in God because of the potential value of living the life of a believer. Still other philosophers have argued that belief in God is not rational. They argue that the cosmos can be sufficiently explained without belief in God and that religious experience is not a valid source of truth. They point to the existence of evil and suffering in the effort to show there is no God, and they argue that life is meaningful enough without a belief in God. The question of whether it is rational to believe in God remains a contested question to this day.

THEOCRACY

The term *theocracy* signifies belief in governance by divine guidance, a form of regime in which religion or faith plays the dominant role. It denotes thus a political unit governed by a deity or by officials thought to be divinely guided. The word *theocracy* originates from the Greek *theokratia*. The components of the word are *theos*, “god,” and *kratein*, “to rule,” hence “rule by god” or “government by god.”

The concept of theocracy was first coined by the Jewish historian Flavius Josephus (37 CE–c. 100 CE). Attempting to explain to Gentile readers the organization and political system of the Jewish commonwealth of his time, Josephus contrasted theocracy with other forms of government, such as monarchy, oligarchy, and republics: “Our legislator [Moses] had no regard to any of these forms, but he ordained our government to be what, by a strained expression, may be termed a theocracy [*theokratia*], by ascribing the authority and power to God, and by persuading all the people to have a regard to him, as the author of all good things” (Josephus 1737).

Few concepts have changed more radically over time than the concept of theocracy. According to its oldest meaning, as used by Josephus, the implication is not that ministers assumed political power. However, according to the more modern definition in the *The Shorter Oxford English Dictionary on Historical Principles*, *theocracy* is “a system of government by sacerdotal order, claiming divine commission” (*The Shorter Oxford English Dictionary on Historical Principles*, vol. 2, 1939, p. 2166), a state in which priests exercise political power, or, more precisely, a state ruled by ministers. In this entry, both meanings will be used.

Theocratic forms of government have existed throughout history. Theocracies were known among ancient people, as in Egypt and Tibet, where kings represented and even incarnated the deity. (In pharaonic Egypt, the king was considered a divine or semidivine figure who ruled largely through priests.) This was the case also with early American civilizations, such as the Mayas, Toltecs, Aztecs, and Natchez.

In Islam, the community established by the prophet Muhammad (c. 570–632) in Medina (622–632) was a theocracy in which Muhammad served as both temporal and spiritual leader. The communities established by Muhammad’s father-in-law and successor, Abu Bakr (c. 573–634), the first caliph, were also based on theocratic government. The largest and best-known theocracies in history were the Umayyad caliphate (the first Islamic dynasty, 661–750) and the early Abbasid caliphate (the second major Muslim dynasty, 750–1258), in which state and religion were closely intertwined; the Byzantine Empire (fourth–fifteenth centuries), in which the emperor was the head of the church; and the Papal States (Stati Pontificii) during the Middle Ages, in which the pope was the ruler in a civil as well as a spiritual sense.

In Christianity during the early modern period in Europe, the republic of Florence under the rule (1494–1497) of Girolamo Savonarola (1452–1498) became a theocracy in which God was the sole sovereign and the Gospel constituted the law. After the Protestant Reformation of the sixteenth century, there were many attempts to establish theocracy. The most famous is the theocratic regime that John Calvin (1509–1564) established in Geneva when he was at the height of his power (1555–1564); Geneva’s civil life was based upon total obedience to God, whose moral order is declared in the scriptures. According to Calvin, a well-ordered Christian community results from a synthesis of rule, cooperation, and order emanating from the divine laws of God; such a community is unified, organized, and structured upon the idea of advancing the glory of God in the world. The same view is evidenced in the theocratic government that Huldrych Zwingli (1484–1531) established in Zurich from 1525 to 1531. In Zurich, the city council was the lawful government of a Christian state (both church and canton) and administrated the divine commands from the Bible. For interpretation of these commands the council sought and acted on the advice of Christian ministers.

With the Puritan migration to New England during the 1630s, theocratic governments were established in what became Massachusetts and Connecticut. For the New England Puritans, theocracy was considered the best form of government in a Christian commonwealth because only this type of government acknowledged Christ as a sole ruler over the people. Spiritually saving grace was the prerequisite for admission to freemanship or citizenship in the Puritan theocracy. The Puritans’ goal was not to invest ministers with political power, but rather to appoint civil magistrates who would govern according to God’s word and will. Only “visible saints,” or those who were able to prove the power of saving grace in their hearts, were allowed to vote, while “the ungodly,” or profane people, were excluded from political power. In England too, during the Puritan Revolution (1640–1660), especially after the execution of King Charles I in 1649, many zealous Puritans strove to establish a theocratic government by introducing a “Sanhedrin of saints,” or a dictatorship of the godly.

In the contemporary world, the regime that Ayatollah Ruholla Khomeini (1900–1989) established in Iran in 1979 is considered a theocracy because political power and authority is held in the hands of the imams or religious leaders. The purpose of such a fundamentalist regime is to organize society exclusively under Islamic religious law, the *sharia*. The Taliban state in Afghanistan
(1996–2001) was similar. In the first decade of the twenty-first century, various fundamentalist Muslim groups are striving to establish theocratic forms of government in Algeria, Pakistan, Egypt, Sudan, Turkey, and other Islamic countries. There are also various fundamentalist Christian groups in the United States, Canada, and Australia who advocate aspects of theocratic government. In Israel, too, several ultra-Orthodox factions advocate restoring the theocracy of ancient times.

THEORY

The notion of a theory is controversial in social science. A single and simple conception of theory is unlikely to apply across all fields, from mathematical economics to cultural anthropology. Still, construing theory broadly as any attempt to systematize and explain certain phenomena, it is clear that theories play a central role in social science. Many social-science pioneers, for example, Karl Marx, Émile Durkheim, Talcott Parsons, Sigmund Freud, Clark Hull, and Paul Samuelson, developed ambitious theories intended to explain a wide range of social phenomena. Today the tendency is toward more modest theories with narrower scope.

Philosophers of science have also adopted a more flexible and eclectic account of theorizing. For much of the twentieth-century, philosophers (and many social scientists) accepted the logical-positivist view that a theory is an axiomatized deductive system consisting of a few basic principles or laws (e.g., Newton’s laws of motion constitute his theory of universal gravitation). These principles contain a theoretical vocabulary describing entities that are often unobservable (e.g., electron, utility, social role), and also bridge laws that link the theoretical vocabulary with observable things. Such theories are tested by deriving predictions from basic principles, bridge laws, and statements describing the test situation, and then determining whether those predictions come true.

By the 1960s, every aspect of the positivist view was under attack, and today few philosophers accept it. The notion of laws has come to play a smaller role in philosophical discussion and that of models a larger one. But there remains no consensus about the nature of theories in the social sciences. Some are still expressed in formal, mathematical terms, with basic principles (axioms) from which predictions are deduced. But many are less formal, with a looser connection between theory, on the one hand, and explanation and prediction, on the other. However, even relatively modest theories can be illuminating. To the extent that a theory allows one to make predictions, it provides some measure of control over the social world. Moreover, some theoretical assumptions are needed to guide exploratory research, or even mere observation, since otherwise there are potentially an infinite number of things that might be relevant.

GOALS OF SOCIAL SCIENCE

Views about the nature of theories in social science go hand in hand with views about the nature of social science itself. Naturalists (e.g., in cognitive psychology) see the social and natural sciences as continuous in their goals and methods. They aim to explain human behavior by uncovering its causal mechanisms. As objects of study, however, people are distinctive because they think about, and so guide, their own actions. Given this sort of agency, some social scientists (e.g., in cultural anthropology) hold that mechanistic theories are inappropriate for studying humans. The point of social-scientific theories is, on this
view, to explain actions by interpreting them so that they are intelligible.

Interpretive scientists hold that we already have a scheme for making sense of human action: People act to get what they want (feel obliged to pursue, and so forth), given what they believe. This common-sense pattern is so fundamental that it is considered to be more than a behavioral hypothesis—it is the standard of intelligibility for action. Interpretation is a sort of translation project—people read the text of other people’s actions. To understand their language one must empathetically immerse oneself in their concerns and situations. Like languages, conceptual schemes have conventions and norms, and fluency in both is the capacity to follow (and exploit) those conventions and norms.

Naturalists need not reject common-sense psychological principles, though historically some (e.g., behaviorists) have. Now, however, most think that it is desirable to integrate reason-based behavior into the natural-scientific picture of the world, and so they seek to find the mechanisms that underwrite common-sense psychology. It now seems clear that a person’s reasons for acting are the causes of her behavior. Causal mechanisms may include preferences, values, habits, reinforcement histories, and the like.

Theories often include terms that ostensibly refer to entities involved in causal mechanisms (e.g., utilities, norms, information flows, social roles). So-called instrumentalists do not interpret such talk literally, but see it simply as a tool for predicting the behavior of individuals (organizations, institutions, societies, and others). They are agnostic about mechanisms—tools should pinpoint what will happen, but they need not say why. Interpreted instrumentally, however, theoretical constructs are fictions that can do no causal work. Hence, many philosophers and social scientists are realists about the entities posited by more successful theories.

Contrary to the views of many early-twentieth-century philosophers, causal explanation does not require appeal to, or even the existence of, precise causal laws. One can explain, for example, that the glass broke because someone dropped it, without knowing any general laws about glass or fragility. Of course some general knowledge about how things break is needed, but it need not add up to a precise exceptionless absolute (or precise probabilistic) law. Such generalizations as we do possess typically describe how a given construct or tendency would operate in isolation (e.g., rational choice theory describes how agents would act if they had clear preferences, coherent subjective probabilities, and acted to maximize their expected utility).

Behavioral mechanisms rarely operate in isolation. Outside the artificial environment of the laboratory, most social phenomena are produced by a wide variety of causal factors that differ from situation to situation and interact with each other in very complicated (frequently nonlinear) ways. Prediction in such cases is usually difficult. Even in physics, prediction is often next to impossible, because many systems of interest are nonlinear and hence chaotic. Pure, idealized cases can provide explanatory insight into the role mechanisms play in the generation of behavior despite their predictive impotence.

With the rejection of the positivist view that prediction and explanation are symmetrical (though with prediction occurring before a predicted event and explanation after the event explained), it is now clear that it is possible to have a theory that is good at one but not the other. For instance, theories that simply extrapolate correlations may be good at predicting without offering much explanatory insight into why the predictions come true. By contrast, many theories in the social sciences can offer explanations after the fact, even though they could not have predicted the phenomena beforehand. Typically they do this by pinpointing (or at least conjecturing about) the causal mechanisms that led to the thing to be explained (e.g., the bear market in U.S. stocks in the early 2000s). Even theories that are better at explaining than predicting are typically tested by their predictive power, however, and both explanatory power and predictive power are clearly desirable.

**THEORY EVALUATION**

Because social-scientific theories rarely underwrite precise predictions (or postdictions), they are often difficult to test. In many cases theories yield only rough qualitative predictions, and these are typically compatible with a number of competing theories. Studies in the real world often allow us to discover correlations among variables (like years of education and income), and a theory gains some support when it makes reasonably precise predictions about the strengths of such correlations. But scientists are often interested in isolating causes, and, as the truism goes, correlation is not causation. Causes are traditionally discovered by carefully designed experiments whose outcomes are evaluated using null-hypothesis significance testing. Such testing, however, has come under increasing fire from methodologists such as Lisa Harlow, Stanley Mulaik, and James Steiger.

Social-scientific theories are useful when they help isolate the mechanisms that subserve behavior. Without some idea about when such mechanisms will be triggered and how they will interact, however, predictive ability is limited. Recent work, such as that of Judea Pearl, attempts to distill causal claims from real-world correlation data (plus a few assumptions about causation). Work on path analysis and other approaches to causal modeling will
probably play an increasing role in testing theories in the future.

**ADMISSIBLE THEORETICAL CONSTRUCTS**

Debates in the social sciences often center around identifying appropriate theoretical constructs. One classical division distinguishes the *Homo sociologicus* and *Homo economicus* pictures of human beings. A third image— *Homo psychologicus*—might be added. The first picture holds, roughly, that people are shaped by their cultures and (mostly) act in accordance with social norms. Central constructs here include norms, values, and social roles. By contrast, *Homo economicus* is a rational calculator who (normally) acts so as to secure desired outcomes. Central constructs here include preferences and subjective utilities. Thus a sociologist might explain crime in terms of the norms of a criminal’s peer group, while an economist might argue that, in the agent’s milieu, crime is the most sensible behavior. Those favoring a *Homo psychologicus* account are more likely to employ information-processing constructs.

No single approach has been notably successful in explaining behavior on its own. Many social scientists agree that each account supplies part of the picture: Norms can influence preferences and beliefs; economic outcomes can influence the evolution of norms and social roles. In practice, however, cooperation among social sciences has proven elusive. Integrating the insights of sociology, economics, psychology, and other social sciences is difficult because each appeals to different properties and processes. Rather than attempt any integration, different theories are often offered as competitors. As a result, disciplines often tend to be identified more with their explanatory approaches than with specific areas of interest. Cross-disciplinary theorizing is an important frontier for social science.

Another historically important debate over appropriate constructs concerns the level at which theoretical concepts and generalizations should be framed. Social scientists disagree about whether their investigations should focus on individuals or groups, but clearly they often do care about the dynamics of social groups. Scientists want to know, for example, how price levels change with world events, not just how individual consumers react. When they look for patterns at this level of aggregation they often find them. Supply shortfalls in crucial commodities result in price increases. Researchers can often detect such regularities without considering the idiosyncrasies of individuals.

French philosopher Émile Durkheim went so far as to argue that there are autonomous social facts and that social explanations should cite social properties rather than appeal to the psychology of individuals. This view has led to much fruitless debate over reductionism and the existence of social facts. Recent philosophy may help to clarify these issues. Higher level patterns are best understood as equilibria resulting from a number of actions. In a market system, for example, general price increases result from the predictable decisions of numerous agents. Accounts of supervenience, such as those by American philosopher Jaegwon Kim, make clear that the truth of generalizations at one level of analysis (e.g., biology) may depend on that of generalizations at a lower level (e.g., chemistry) without being translatable into the latter. These accounts permit reconciliation of the claim that social phenomena would not exist without the actions of individual agents with the claim that many important generalizations can only be framed in vocabulary that does not involve specific individuals.

FOLK PSYCHOLOGY AND APE PSYCHOLOGY

Consider, for example, how biological and physical motions are perceived. The motion of a falling apple is governed by Newton’s laws, and human infants as young as three months are sensitive to violations of such principles (Spelke 2000). In contrast, most human behaviors are interpreted in terms of desires, beliefs, and emotions. As a classic demonstration of how far we are ready to stretch our folk psychology, Fritz Heider and Marianne Simmel (1944) showed undergraduate students animation movies in which geometric figures moved in coordinated ways that strongly hinted intentional behaviors such as avoidance or helping. When asked to describe the scenes, participants did not hesitate to apply mentalistic attributes to circles and triangles.

Contemporary interest in ToM, however, was sparked by the mind-reading ability of Sarah, a fourteen-year-old chimpanzee who appeared to recognize intentions from behaviors. In a groundbreaking paper titled “Does the Chimpanzee Have a Theory of Mind?” (1978), David Premack and Guy Woodruff showed Sarah video vignettes of a trainer attempting in vain to achieve a goal (e.g., to exit a cage through a locked door) and then a pair of photographs depicting potential solutions (e.g., an intact key along with a broken one). Spontaneously, Sarah “recognized the videotape as problem, understood the actor’s purpose, and chose alternatives compatible with that purpose” (Premack and Woodruff 1978, p. 515). The authors attributed her success to the existence of a system that represents mental states, such as desire and intent, and links them to behaviors. They further maintained that “a system of inferences of this kind may properly be viewed as a theory because such states are not directly observable, and the system can be used to make predictions about the behavior of others” (p. 515).

Some thirty years later, the field remains divided over whether chimpanzees (or any nonhuman primates) possess a theory of mind or simply a theory of behaviors. Michael Tomasello and colleagues argue that the great apes understand others as “animate, goal-directed, and intentional agents” (2005, p. 675) even though they fall short in understanding beliefs and other mental states compared to humans (Call and Tomasello 1999). Others, however, caution that we have to first rule out the possibility that their responses are based on behavioral regularities (Heyes 1998; Povinelli and Vonk 2003, 2004). For example, chimpanzees spontaneously follow the gaze of others (Okamoto et al. 2002) and are attuned to what others can or cannot see (Hare et al. 2000; Povinelli and Eddy 1996). Nevertheless, it is unclear whether chimpanzees can link seeing to knowing. When competing for food, subordinate chimpanzees are reported to keep track of what dominant chimpanzees know and do not know about food locations (Hare et al. 2001). This is in stark contrast with an earlier finding that chimpanzees would beg for food indiscriminately from both trainers who could see and those who had a bucket over their head (Povinelli and Eddy 1996).

The current debate on ToM in nonhuman primates is not about whether they are capable of sophisticated social behaviors—yes, their abilities to keep track of and manipulate others sometimes rival those of humans. The issue is what can be concluded when their behaviors are compatible with both a ToM and a theory of behavioral regularities. Until a consensus is reached on this and other critical issues, the question Premack and Woodruff famously raised in their seminal work will remain unanswered.

FALSE BELIEFS AND THE DEVELOPMENT OF TOM IN HUMAN CHILDREN

In comparison, a consensus did emerge among developmental psychologists. It was suggested that an understanding of “false beliefs” is a sufficient condition for a ToM, because beliefs—unlike behaviors—are private and unobservable, and thus are beyond the scope of a theory of behaviors (Dennett 1978). And thanks to language, beliefs can be identified unequivocally in human participants.

This idea was put to a test by Heinz Wimmer and Josef Perner (1983) when the researchers told young children a story in which Maxi put his chocolate in a kitchen drawer and left. In his absence, Maxi’s mom moved the candy to a different drawer. Children had to predict where Maxi would look for his chocolate on his return. While most six-year-old children correctly predicted Maxi’s action on the basis of his false belief that the candy was still in the original drawer, most four- and five-year-old children in this study expected Maxi to look in the new location.

Young children’s difficulties are not limited to thinking in other people’s shoes. They appear to be oblivious about false beliefs they held a few moments earlier (Gopnik and Astington 1988). The development of ToM is remarkably consistent and robust, progressing almost uniformly from appreciating that people have different desires to understanding false beliefs, and later to differen-
tiating apparent versus true emotions (Wellman and Liu 2004). A meta-analysis of more than 170 false-belief studies concluded that the transition in false-belief understanding takes place in the preschool years for most children (Wellman et al. 2001).

Although passing the false-belief task attests to a ToM, the converse is not true (Bloom and German 2000). For example, younger children may fail due to their inability to inhibit improper responses (Leslie et al. 2004; Leslie and Polizzi 1998). In addition, children show a range of competences before they pass the false-belief test. At three months of age, infants prefer biological motion to random motion (Bertenthal et al. 1984) and shift their eye gaze after an adult makes an eye movement (Hood et al. 1998). At around twelve months, human infants begin to follow others’ line of sight and predict actions according to gaze (Sodian et al. 2004). The second year of life sees the onset of joint visual attention (Butterworth and Jarrett 1991), imitation (Meltzoff 1995), and pretend play (Lillard 2002). There is even evidence that sixteen-month-old infants have an implicit understanding of false beliefs (Onishi and Baillargeon 2005). From three to five, children produce mental words such as think or want, start to appreciate jokes (Leekam 1991), and attempt to deceive (Sodian et al. 1991). ToM continues to develop; adults still fall victim to egocentrism from time to time (Keysar et al. 2003). Nonetheless, the basic apparatus for reading and reasoning about mind is largely in place early in childhood.

THEORIES OF THEORY OF MIND

What explains children’s initial failure and later success in the false-belief task? The theory theory postulates that we reason about mental events based on a system of heuristics or if-then rules (Gopnik and Wellman 1994). The child actively constructs and revises the informal ToM based on experience. For instance, a toddler may begin with a prediction that if Maxi wants something, he will act to satisfy his desire. Experiences with false beliefs of others or herself will force the child to abandon this simple heuristic and incorporate belief into an adultlike theory of mind (Bartsch and Wellman 1995).

The notion of a theory as the basis for mind reading is challenged by the simulation theory, which proposes that we compute others’ mental states through an automatic role-play simulation (“if I were him …”; Gallese and Goldman 1998; Gordon 1986). Young children find the impersonation difficult in a false-belief task because one has to withhold one’s own belief and instead reason with the erroneous belief of the person to be simulated.

If a child has to discover a ToM completely on his or her own, as suggested by the theory theory, the acquisition is unlikely to be consistent and universal. Two solutions have been proposed in the literature. One is the hypothesized theory of mind mechanism (ToMM; Leslie et al. 2004; Baron-Cohen 1995), an innate neurological module that automatically maps behaviors of self-propelled agents to mental states and vice versa. The ToMM is thought to mature fairly early in life and kick off the subsequent development of folk psychology. Young children’s difficulty with the false-belief task is attributed to immature executive functioning, which works in conjunction with ToM to make behavioral predictions.

An alternative view traces the origin of ToM to language and culture. Everyday conversations expose children to the fact that speakers may have different knowledge and beliefs. Language also provides specific lexical terms for mental states (e.g., see, know, and want) and, in some cases, different syntactic structures for different mental states (e.g., “I want to …” but not “I want that…”; however “I know that …” but not “I know to…”; see de Villiers and de Villiers 2000). These linguistic structures invite children to think about mental events in a way that is conventional in the language community. In this perspective, language and culture provide both the blueprint and building blocks for developing a ToM (Astoning and Baird 2005).

MINDBLINDNESS AND BRAIN IMAGING

What would the world be without a ToM? Childhood autism is a spectrum of pervasive developmental disorders characterized by deficits in social interaction, verbal communication, and repetitive behaviors. Simon Baron-Cohen and colleagues (1985) hypothesized that autistic children have a severe deficit in the ToMM. For example, Baron-Cohen (1995) showed children a face (“Charlie”) surrounded by four different kinds of candy, with Charlie’s eyes looking toward one of them. When asked “which candy does Charlie want,” most four-year-olds pointed to where Charlie was gazing. In contrast, children with autism responded randomly to what Charlie wanted, even though they had no trouble answering where Charlie was looking. The problem is a failure to map perception to mental states. Niki L, a high-functioning autistic person, wrote:

Many [autistic persons] lack some sort of intuition and have a hard time guessing hidden rules many [normal] kids somehow see…. I think I eventually formed a relatively good theory of mind, but it took intentional effort. And I still have to apply it manually. It gets faster and faster as I collect many patterns in my memory, but I’m afraid it won’t be automatic forever. (Blackburn et al. 2000)
Brain imaging has begun to shed light on the potential neural mechanism underlying ToM. For example, Kevin Pelphrey and colleagues (2005) reported functional MRI evidence that participants with autism are insensitive to intentions conveyed by other people's eye movements. Other imaging studies contrasted brain activities while processing mental versus physical events, for example, listening to stories involving rich mentalizing (Fletcher et al. 1995; Gallagher et al. 2000; Vogeley et al. 2001) or watching Heider/Simmel-like cartoon animations (Castelli et al. 2000). Consistently, stronger activations are found in the medial prefrontal cortex (MPFC), temporal poles, and the posterior superior temporal sulcus (STS) during mentalizing. For further information, see Frith and Frith (2003) and Baron-Cohen et al. (2000).

CONCLUSION

The prepositional phrase theory of mind is a linguistic oddity. Contrary to the expectation of a native English speaker, for example, the “theory of mind mechanism” is not a theory about “mind mechanism” but a mechanism for theory of mind. The strong internal cohesiveness reflects a commitment to two of its core assumptions—that behaviors are understood in mental terms and that this understanding constitutes a theory.

Although both points are under vigorous debate, ToM as a field of scholarship has thrived, and continues to thrive, beyond the imagination of Premack and Woodruff (1978). Recent reports of self-recognizing elephants and dolphins (Plotnik et al. 2006; Reiss and Marino 2001) and deception in scrub jays (Dally et al. 2005), among others, question the view that ToM is unique to a handful of primate species—if not for humans only—and instead suggest similar competences have evolved independently as an adaptation to complex social lives. Meanwhile, computer scientists find ToM essential in developing autonomous, cooperative robotic agents (Scassellati 2002), and economists are tying many aspects of social exchange and decision making to ToM (Singer and Fehr 2005). This brief survey of ToM cannot do justice to a vast and vibrant field of study. But fortunately, motivated readers should not have difficulty finding in-depth and up-to-date readings that connect ToM with their specialty—after all, where there is social interaction, there is theory of mind. At least potentially.

**THEORY OF SECOND BEST**

Consider a stylized economy in which all markets are perfectly competitive, there are no distortions, no externalities, and no public goods. All resources are privately owned and all agents maximize their respective welfare, consumers maximizing utility and firms maximizing their profit. All individuals possess perfect information and there are no impediments to trade so that all markets always clear (i.e., the quantity of goods supplied always equals the quantity of goods demanded). The resulting equilibrium in this idealized world is characterized by a set of optimality conditions, known as Pareto optimality conditions. This equilibrium is said to be a first-best optimum in which there is no welfare-improving role for government policy.

In a seminal paper published in 1956, Richard Lipsey and Kelvin Lancaster considered the consequences of introducing into this general equilibrium system a constraint (or distortion) that prevents one or more of the optimality conditions characterizing the first-best optimum from being attained. For example, suppose a firm has monopoly power, causing it to set a price above marginal cost, thus violating one of the conditions for the first-best equilibrium to prevail. Lipsey and Lancaster then showed that while the other optimality conditions characterizing the first-best outcome may still be attainable, in general it is no longer optimal to impose them. In other words, if one of the Pareto optimality conditions cannot be fulfilled, a second-best optimum is achieved only by deviating from all other optimality conditions.

This proposition has profound implications. First, the simple intuitive efficiency conditions characterizing the first-best optimum are replaced by complex nonintuitive optimality conditions characterizing the second-best equilibrium. Consequently in general nothing can be inferred about either the direction or the magnitude of the deviations of the second-best optimum from the first-best outcome. That depends upon the entire underlying economic structure and the extent to which the distortions relate to the rest of the economy. Second, the optimality conditions may introduce nonconvexities, which call into question whether the equilibrium is indeed an optimum. Third, the existence of such constraints restores a potential welfare-improving role for economic policy.

Although the concept of "second best" is identified primarily with Lipsey and Lancaster, it in fact appeared in the economics literature well before that time. References to it in the context of free trade versus protection can be found as early as the beginning of the twentieth century in the Italian economist Vilfredo Pareto’s original work on general equilibrium theory, while the concept is also discussed by Paul Samuelson in his 1947 book *Foundations of Economic Analysis* and in more detail by James Meade in his 1955 publication *Trade and Welfare*. The main contribution of Lipsey and Lancaster is to provide a more formal analysis of the concept and to highlight the consequences for policy makers.

**IMPEDEMENTS TO FIRST-BEST OPTIMUM**

Several types of distortions may prevent the first-best Pareto optimal outcome from being attained. Some, such as returns to scale (the relationship between proportionate changes in inputs and the resulting change in output), are technological in nature; while others, such as monopolistic market structures and barriers to entry, may be created by the private sector. These distortions may be neutralized, at least in part, by some form of government intervention. In some cases this may take the form of economic incentives, designed to discourage the behavior causing the distortion, while in other cases it may simply be an outright legal restriction. It is also possible for the government itself to be the source of the distortion. The need to provide public goods, financed by a distortionary tax, such as an income tax, is a familiar example.

While, as Lipsey and Lancaster highlighted, externalities and distortions generally lead to divergences from the Pareto optimal outcome, simple examples also exist where no divergence is created. For example, in their 2005 study Wen-Fang Liu and Stephen Turnovsky considered a neoclassical growth model with an inelastic labor supply in which utility depends upon the agent’s own consumption, together with economy-wide average consumption, a potential distortionary effect. They show that while the consumption externality influences the economy’s time path for capital accumulation, for a widely employed class of utility functions it causes no deviation from the Pareto optimal time path.
